</tbody>
</table>

The following are new programming commands for VNA release A.12.85.xx See What's New.

Dark shaded commands existed before this release. They are provided here for convenience.

Automatic Fixture Removal (AFR)

Selects whether the fixture is band limited or not.

<table>
<thead>
<tr>
<th>Command</th>
<th>SCPI</th>
<th>COM</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFR:FIXTure:BLIMited[:STATe]</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Selects whether to use DUT correction or not when the characterization fixture is not equal to the DUT measurement fixture.

<table>
<thead>
<tr>
<th>Command</th>
<th>SCPI</th>
<th>COM</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFR:FIXTure:CDUT[:STATe]</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Selects Fixture Length A not equal to B correction.

<table>
<thead>
<tr>
<th>Command</th>
<th>SCPI</th>
<th>COM</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFR:FIXTure:CLENgth[:STATe]</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Selects Fixture Match A not equal to B correction.

<table>
<thead>
<tr>
<th>Command</th>
<th>SCPI</th>
<th>COM</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFR:FIXTure:CMATch[:STATe]</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Describes the fixture inputs (single ended or differential).

<table>
<thead>
<tr>
<th>Command</th>
<th>SCPI</th>
<th>COM</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFR:FIXTure:INPuts</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Selects the number of fixtures to be characterized.

<table>
<thead>
<tr>
<th>Command</th>
<th>SCPI</th>
<th>COM</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFR:FIXTure:MEASurement</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Refreshes preview data.

<table>
<thead>
<tr>
<th>Command</th>
<th>SCPI</th>
<th>COM</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFR:FIXTure:PREView</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Reads the impedance profile of the calculated fixture model.

<table>

The following are new programming commands for release A.12.50.01.

**Memory Interpolation**
- Generate a new ENR file by embedding an adapter to an existing ENR file.
  - CSET:FIXTure:ENR:EMBed
  - ENREmbedAdapter
- Read S parameter of ECal Thru from the ECal memory and save it as s2p file
  - SYSTem:COMMunicate:ECAL:EXPort:SNP
  - OutputSNPFromECal Method

The following are new programming commands for PNA release A.10.49.05.xx See What's New.

**Memory Interpolation**
- Sets and reads the state of the memory data interpolation
  - CALC:MATH:INTerpolate
  - InterpolateMemory
- Sets and reads the state of the memory data interpolation default preference
  - SYST:PREF:ITEM:MINTerpolate
  - InterpolateMemoryIsDefault

**External DC Device**
- Sets and returns the current limit value
  - SYST:CONF:EDEV:DC:LIMit:CURRent
  - CurrentLimit
- Sets and returns the voltage limit value
  - SYST:CONF:EDEV:DC:LIMit:VOLTage
  - VoltageLimit
Error Correction Terms
Computes the error correction terms, turns Correction ON, and saves the SENS:CORR:COLL:GUID:ETER:COMPute calibration to an existing, specified Cal Set

The following are new programming commands for PNA release A.10.49 See What's New.

Dark shaded commands existed before this release. They are provided here for convenience.

Setup Options

Uncertainty Options

- **Calibration Options**
  - **Noise**
  - **Repeatability**
  - **Standard Definition**

- **Max Uncertainty Points**: 500

Service Mode

[OK] [Cancel]

- **SYST:UNC:ETER:NOIS:ENAB** PortNoiseEnabled
- **SYST:UNC:ETER:CABL:REP** CableRepeatabilityEnabled
- **SYST:UNC:ETER:SDEF** StandardDefinitionsEnabled
- **SYST:UNC:POIN:MAX** MaximumUncertaintyPoints

Noise Characterization

- Clear noise data on specified port: **SYST:UNC:PORT<p>:NOIS:RESet** ResetNoise
- Clear noise data on all ports: **SYST:UNC:PORT:NOIS:RESet** ResetNoiseForAllPorts
- Copy noise from a port to all ports: **SYST:UNC:PORT:NOIS:ALL:COPY** CopyNoiseToAllPorts

Cables Characterization

- List cables: **SYST:UNC:CABL:CATalog?** Cables Collection
- Assign Cable to all ports: **SYST:UNC:PORT:CABL:ALL** SelectCableForAllPorts
- Assign Cable to specified port: **SYST:UNC:PORT<p>:CABL:e** Cable
- Reset repeatability: **SYST:UNC:CABL:REP:RES** ResetRepeatability

Uncertainty workspace

- Load workspace: **SYST:UNC:LOAD** Recall
- Save workspace: **SYST:UNC:STORe** Save

Enabling a Guided Calibration to include Uncertainties

- Checkbox on Guided Cal Select Ports page: **SENS:CORR:COLL:GUID:UNC** UncertaintyEnabled

</tbody>
</table>
## Calibrations

Returns the names of the mechanical cal kits for unguided calibrations.

Set/get by name which cal kit is currently selected for use by unguided cal.

Read pass fail status of tolerance limits on the target cal power

Gets the power correction dB values from the prior iteration of the source power cal.

**ECal User Char to Disk (new and modified commands)**

Returns the factory defined and user-defined connectors.

None

Initiate a User Char - optionally check module memory.

*SENSe:CORR:CKIT:ECAL:CHAR:INIT*  
InitializeEx

Saves a new characterization to disk memory

*SENSe:CORR:CKIT:ECAL:CHAR:DMEM:SAVE*  
SaveToDiskMemory

Delete disk memory characterizations.

*SENSe:CORR:CKIT:ECAL:DMEMory:CLEar*  
None

Saves a disk memory characterization to an archive file.

*SENSe:CORR:CKIT:ECAL:EXPort*  
None

Imports the ECal characterization from the specified archive file.

*SENSe:CORR:CKIT:ECAL:DMEMory:IMPort*  
None

Reads the user-characterization info from ECal module or PNA disk memory.

*SENSe:CORR:CKIT:ECAL:KNAM:INF?*  
None

**Gain Compression Analysis**

Enable a compression analysis trace

*CALC:GCM:ANAL:ENAB*  
AnalysisEnable

Set CW frequency

*CALC:GCM:ANAL:CWFR*  
AnalysisCWFreq

Set to discrete or interpolated CW frequencies

*CALC:GCM:ANAL:ISD*  
AnalysisIsDiscreteFreq

Sets X-axis display

*CALC:GCM:ANAL:XAX*  
AnalysisXAxis

**Miscellaneous**

Red Segment on Limit Line failures.

*SYST:PREF:ITEM:RTOF*  
RedTraceOnFail

Returns the X-axis values for the selected trace.

*CALC:X?*

Saves a Cal Kit to a file.

*SENSe:CORR:CKIT:EXP*  
GetCompatibleCalKits

Returns the list of cal kits that use the specified connector.

*SENSe:CORR:COLL:GUID:CKIT:CAT?*  
GetCompatibleCalKits

Gain Compression Saturation level

*SENSe:GCS:COMP:SAT:LEV*  
SaturationLevel

Set Cal FOM Range Preference

*SENSe:CORR:PREF:CAL:RANG*  
FrequencyOffsetRangeForCalComputations
Return the Calset X-axis FOM frequency range

SMC - perform separate power cals

**Noise Figure Setup**

Create Noise figure meas

Sets the number of impedance states to use

Noise averaging ON and OFF

Set averaging of noise receiver.

Set bandwidth of noise receiver.

Set gain state of noise receiver.

Sets noise tuner identifier

Sets the port identifier of the ECal noise tuner that is connected to the PNA Source.

Sets the port identifier of the ECal noise tuner that is connected to the DUT.

Set the excess noise source ON or OFF.

Set mechanical switches

Sets the default setting for the Noise Tuner switch.

**Noise Figure Cal**

Create Noise Cal object

Set Noise Calibration method

Noise source ENR filename

Set noise source Cal Kit type

Set ambient temperature

Sets noise source connector type

Set Noise source temperature

COM versus SCPI

There are two methods you can use to remotely control the VNA: COM and SCPI. The following topics can help you choose the method that best meets your needs:

- Software Connection
- Physical Connection
- Programming Languages

Other Topics about COM Concepts

Software Connection

COM uses a binary protocol, allowing you to directly invoke a VNA feature. This is more efficient than SCPI. For example, the following statement calls directly into the VNA, executing the routine GetIDString.

```
PNA.GetIDString()
```

SCPI is a text based instrument language. To retrieve the ID string, you would send the following text string to the VNA:

```
IbWrite("*IDN?")
```

The VNA SCPI parser would first decode this text string to determine that the user has asked for the VNA to identify itself. Then the parser would call the COM method GetIDString().

The Physical Connection

Internal Control

With either COM or SCPI, the best throughput is attained by using the VNA's internal PC to execute your test code. However, if your test code uses too much system resources (CPU cycles and/or memory), this will slow the VNA's performance.

Using the SICL I/O Libraries, you can also connect to the VNA from a program running on the VNA.

External Control

You can control the VNA from a remote PC using either COM or SCPI.
**COM** - (Component Object Model) can be used to access any program like the VNA (835x.exe) or library (.dll) that exposes its features using a COM compliant object model. These programs or libraries are called "servers". Programs (like your remote program on your PC) that connect to and use the features of these servers are called "clients."

With COM, the server and the client do not need to reside on the same machine. DCOM, or distributed COM, makes the location of the server transparent to the client. When you access the VNA from a remote computer, you are using DCOM. In this case, the mechanical transport is a LAN (local area network).

However, using COM can add additional complexity:

- There are some DCOM security issues that may be a problem for you. Learn more.
- Using the default interface when compiling type libraries results in code that will only run with the latest firmware. Learn more.

**SCPI** - Using a GPIB interface card in a remote computer, you can connect to the instrument using a GPIB cable. There are some constraints on the length of this cable and the number of instruments that can be daisy-chained together.

Using the Keysight SICL I/O libraries, you can connect to the instrument over a LAN connection.

(LAN or INTERNAL) You can send SCPI commands using COM with the `ScpiStringParser` object.

If you have legacy code written in SCPI for another network analyzer, you may be able to leverage that code to control the VNA. However, the VNA uses a different platform than previous Keysight Network Analyzers. Therefore, not all commands have a direct replacement. See the VNA Code Translator Application.

**Programming Languages**

You can program the VNA with either COM or SCPI using several languages. The most common include:

**Keysight VEE** - With this language you can send text based SCPI commands and also use automation. VEE 6.0 or later is recommended.

**Visual Basic** - This language has great support for automation objects and can be used to drive SCPI commands. The use of VISA drivers for your GPIB hardware interface will make the task of sending SCPI commands easier.

**C++** - This language can do it all. It is not as easy to use as the above two, but more flexible.
Remotely Specifying a Source Port

In the 'not-too-distant past', it was a simple task to specify a VNA source port. It was either port 1 or port 2. Now, for the following reasons, it is not so simple:

- **Internal 2nd sources** are now offered on various VNA models. However, some source ports do not have a port number. One example is the second source on the PNA-X 2-port model (option 224). Learn more about Internal Second Sources.

- **External sources** can now be controlled by the VNA as though they are internal sources. External sources do not have a source port number, but use String names as identifiers.
  
  - **For FCA ONLY**: Once configured using the Configuration dialog, an external source can be selected remotely and controlled by the VNA by specifying the LOName using SCPI or COM.
  
  - **All other uses for External sources**: The external source must be configured and selected from the External Source dialog. You can then save an Instrument State file, then recall that state file remotely.

- **Multiport test sets**…choose between ports 1 through port N, where N is the number of ports on the test set. You still use a port number, but this port number refers to a logical port. The Port mapping feature maps the logical port to a physical port. Learn more about Multiport test sets.

- **iTMSA (Opt S93460A/B)** When this option is present, the string names for balanced source ports are returned with the appropriate COM and SCPI commands. For example, "SE Port 1" is used to access 'Single-ended Port 1".

Source Port String Names

The VNA User Interface (UI) makes it easy to configure and select the sources and ports. Remotely however, string names are used now, in addition to port numbers, to specify a Source port.

**COM** - The existing COM commands specify source ports as numbers and they are still used. It is necessary to learn the port number from the string using the GetPortNumber Method. Port numbers are assigned dynamically depending on whether external sources are selected and the number of ports of the VNA.

- **SourcePortNames Property**
- **GetPortNumber Method**
- **SourcePortCount Property**

An example:

```plaintext
dim app = 5700
```
set app = CreateObject("Agilentpna835x.application")
dim channel
set channel = app.Channel
dim portnum
portnum = Channel.GetPortNumber("Src2 Out1")
app.CreateMeasurement 1,"A",portnum

**SCPI** - ALL of the existing SCPI commands that specify a source port are extended to also allow the source port to be specified using string names. For example, send the following command to set the power on Src2 Out1:

- SOUR:POW 5, "Src2 Out1"
- Use Source:Cat? to list the available source port string names.
Shut Down the VNA Remotely

Shut down the VNA remotely by creating and then executing a macro.

Learn more about Macros in the VNA

Create the Macro

1. Click Utility, then Macro, then Macro Setup
2. In the Macro Setup dialog, select a blank line, then click Edit.
3. In the Edit Macro dialog:
   a. Under Title, enter Shutdown
   b. Under Macro Executable, enter Shutdown
   c. Under Macro run string parameters, enter -s -t 0 This will wait 0 seconds before executing the command.

Execute the Macro Remotely

Send the following SCPI command:

- `SYST:SHOR<n>:EXEC` where `<n>` is the number (formerly 'blank' line) of the macro that is stored in the VNA.

Variations

To see variations on this command, on any Windows computer:

- From any command prompt, enter `help shutdown`
The VNA has code emulators that allow you to control the VNA using test programs written in the remote control commands of the 8753. The code emulators process each of incoming 8753 commands in real time, by first recognizing it as a valid command, and then executing the VNA’s equivalent command(s) if one exist. The 8753 command emulation is performed by the CxL Application.

The CXL Application will also help translate your Legacy programs into VNA SCPI and COM commands.

You can launch these code emulators as follows:

1. Press **System > System Settings > Code Emulation**.
2. Select your required model. (To execute 8753, CXL application should be installed on the VNA.)

See the following document for operation.

- CxL Help from Windows Start menu

### Installing the CXL Application

Download the CXL application from [http://na.support.keysight.com/pna/cxl.html](http://na.support.keysight.com/pna/cxl.html). To install the CXL application, double click on the InstallShield package icon.

The CXL application has its own help file that includes a command cross-reference for 8510/8753/872x models to VNA commands.
Using Fixture Simulator

Fixture simulator allows user to mathematically add (embed) or remove (de-embed) circuits to, or from, the measurements. Learn more on Fixture Simulator.

In the new fixture generator with the firmware A.14.40 and above, multiple fixturing elements can be combined in any order, creating infinite combinations. New SCPIs are created with the concept of fixture “blocks’ or “circuits”.

In the legacy fixturing, a few specific features are tied to specific ports.

See Also

- Programming examples:
  - Create fixturing function (impedance conversion and port matching)
  - Create fixturing function (2-port deembed, port extension, port matching, impedance conversion)
  - Create fixuring function (port impedance conversion and port extension)

Concepts

There are two important concepts:

1. Fixtures are built from right to left, the circuit elements are added from right to left. There is no way to insert a block to the right of already existing blocks. And unlike legacy commands, there is not one SCPI command to change the order of the features. Instead, the blocks must be created in the order desired.

   Example of a fixture:
When building a fixture, the circuit elements are added from right to left. So in this example, the S2P blocks are added first, and then the S4P blocks.

**Note:** These blocks always exist and user cannot create them. In order to move them to the appropriate place in the fixture, first create the fixture elements to the right, then send the “calc:fsim:draft:extension:port[n]:end” command to move the port extension to the left-most side of the circuit sections. If more fixture elements are desired to be added to the left of the port extensions, create them after the “calc:fsim:draft:extension:port[n]:end” command is sent.

2. Fixture elements are built on a “draft” fixture and then “applied”. The process should be:
   a. First “discard” the draft fixture changes with **CALC:FSIM:DRAFT:DISCard** command. This copies the active fixture to the draft fixture.
   b. Then build fixture using new **Fsimulator Draft SCPI commands**.
   c. Lastly “apply” the draft fixture with **CALC:FSIM:APPLY**. This does a fixture computation (to ensure validity) and then the fixture is copied to the active fixture in the channel.

**New SCPI commands**

- **Fsimulator Draft SCPI commands, CALC:FSIM:DRAFT:XXX:YYY:ZZZ**: These commands are used to query and
set fixture values on a scratch fixture.

- **Fsimulator Active SCPI commands, CALC:FSIM:XXX:YYY:ZZZ:** These commands are used to query ONLY fixture values on the active fixture.
  
  - The only exceptions to these commands are:

  1. **CALC:FSIM:APPLY** which is same as legacy command
  2. **CALC:FSIM:POWer:PORT:COMPensate** commands because they are not fixture building commands, but rather specify if the fixture is being used in the channel (and how).

- **CALC:FSIM:APPLY:** Validate scratch fixture, copy to active fixture
- **CALC:FSIM:DRAFt:DISCard:** Discard scratch fixture changes by copying active fixture to scratch fixture.
- **CALC:FSIM:RESet:** Preset the fixture.

### Notes

- Legacy SCPI commands will continue to work, but they are incompatible with the new features. There will be an error if legacy SCPI commands are sent after new SCPI commands are sent or and/or after the new GUI is used to build the fixture.

- Blocks are created by default as "de-embed". User must send the **CALC:FSIM:DRAFt:CIRCuit[n]:EMBED:TYPE embed** command to switch to "embed" type.

- In many cases, « CALC:FSIM:DRAFt:CIRC » can replace the legacy-specific SCPI such as « CALC:FSIM:SEND:DEEM:PORT », but it is recommended to read the SCPI documentation linked above.

- To verify that the fixture has been properly created using SCPI, you can visualize the entire fixture by using the new Fixture GUI. Learn more about the Fixture generator dialog box.

- User also can create .topo or .snp file by GUI, and recall the file from SCPI. Learn more on Fixture generator dialog box.

Active Hot Parameters

This application measures the optimum Gamma that provides the maximum delivered power for nonlinear devices. Unlike classic S-parameters, which capture only linear device behavior and ignore nonlinear behavior, X-parameter terms (Xf, Xs, Xt) are used to predict the Gamma that yields the optimum power delivered to a load from a nearly matched device under large-signal drive and thus define the nonlinear behavior of the DUT.

The X-parameter terms assume the following:

- Fundamental frequency (harmonics ignored)
- Amplifier is nearly matched to 50 ohms. The spectrally linearized X-parameters (Xs and Xt terms) are sufficient for characterizing the effects of incident A2 waves while the nonlinear component is driven with a large A1 signal at the input port.

  - Active Parameter X-axis tab
  - Active Parameter Analysis dialog
- Accessing Measurement Parameters
- Calibrating an Active Parameter Channel
- Saving Data

Features and Requirements

Features

- Proper corrections for matched amplifiers operating in nonlinear (Compression, Saturation) region by using fundamental X-Parameters measurements (XS, XT, XF) of the DUT.
- Ensures system-to-system correlation across different test stands.
- Provides fast measurements of the Hot S22, Hot S21 of the DUT.
● Easy calibration and measurement setup. Comb generator is not needed for calibration.

● Provides measurements of the optimum match for maximum delivered power and the value of the maximum power, as well as, power delivered to 50 ohms.

● Uses X-parameter technology to solve the non-linear X-parameter equation (restricted to 50 GHz for option S93111A/B):

\[
\begin{align*}
b_1 &= XF_{11}(|a_1|)e^{i\varphi(a_1)} + XS_{12}(|a_1|)a_2 + XT_{12}(|a_1|)e^{i2\varphi(a_1)}\text{conjugate}(a_2) \\
b_2 &= XF_{21}(|a_1|)e^{i\varphi(a_1)} + XS_{22}(|a_1|)a_2 + XT_{22}(|a_1|)e^{i2\varphi(a_1)}\text{conjugate}(a_2)
\end{align*}
\]

For option S93111A/B, characterization above 50 GHz uses active source injection at device input and output to solve the traditional linear S-parameter equation:

\[
\begin{align*}
b_1 &= S_{11}a_1 + S_{12}a_2 \\
b_2 &= S_{21}a_1 + S_{22}a_2
\end{align*}
\]

Requirements

● Active Hot Parameter software for “B” model PNA-X (N524xB)
  o S93110A/B, Active Hot Parameters
  o S93111A/B, Active Hot Parameters, restricted to 50 GHz
  ● 4-Port PNA-X with 2 sources

Measurement Parameters

● IPwr, Input power - incident power \(|a_1|^2\).
● OPwr, Output Power - output power delivered into Z0.
● HotS11, Active input match \(|XF_{11}(|a_1|)/|a_1|\).
● HotS21, Active Gain – Non-linear gain measured in Z0 \(|XF_{21}(|a_1|)/|a_1|\).
● HotS12, Active Reverse Isolation \((XS_{12})\).
● HotS22, Active Output Match – Conjugate of the optimum load, Gamma.
● Gamma, Optimum load for maximum delivered power.
● Pmax, Maximum delivered power.
● Xs(2,2), Direct Reflection Coefficient. The fundamental XS22 parameter which is used, in combination with XT22, to describe the change in b2 as a function of a2, the signal reflected from the load.
● Xt(2,2), Direct Reflection Coefficient. The fundamental XT22 parameter which is used, in combination with XS22 to describe the change in b2 as a function of a2, the signal reflected from the load.
● Xf(2,1), Output Coefficient. The fundamental XF21 parameter.
- **DeltaOPwr**, Delta between the output wave and output power to Z0 load.
- **Option S9311A/B Only**
  - **HotGain**, Forward Gain using output/input linear S-parameter measurements.
  - **HotMatch**, Output Match using linear S-parameter measurements.
  - The following traces are restricted to 50 GHz: OPwr, HotS11, HotS21, HotS12, HotS22, Gamma, Pmax, Xs(), Xt(), Xf(), DeltaOPwr.

### How to Make Active Parameter Measurements

#### Create an Active Parameter Channel

1. On the VNA front panel, press **Meas > Main > Meas Class**.
2. Select **Active Parameters**, then either:
   - **OK** to delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.
3. An **Active Parameter** measurement is displayed.

#### Configure Active Parameter settings

<table>

</thead>
<tbody>
<tr>
<td>1. Press <strong>Freq &gt; Main &gt; AHP Setup</strong></td>
<td>1. Click <strong>Stimulus</strong></td>
</tr>
<tr>
<td></td>
<td>2. Click <strong>Frequency</strong> then select <strong>ACTS Frequency</strong>...</td>
</tr>
</tbody>
</table>

**Active Parameter Sweep** tab help
Sweep Type - Sets the sweep type to the active channel:

**Linear Frequency**  Sets a linear frequency sweep that is displayed on a standard grid with ten equal horizontal divisions.

**Log Frequency**  The source is stepped in logarithmic increments and the data is displayed on a logarithmic x-axis. This is usually slower than a continuous sweep with the same number of points.

**Power Sweep**  Activates a power sweep at a single frequency that you specify. Learn about power sweep.

**Multisweep**  Selects multiple sweep. This is also called 3D sweep (power, phase, and frequency). Each sweep can be set to a different power level. Within each sweep is a 2D sweep of phase and frequency. With a fixed input power, a frequency-swept trace is useful to analyze the DUT’s frequency response. With fixed input power and fixed frequency, offset-phase measurements are performed to get adequate values to compute the “active S22” and X parameters.

**Linear/Log Frequency Sweep Type**
Source

- **Start Frequency**  Sets the beginning value of the frequency sweep.
- **Center Frequency**  Sets the center frequency of the frequency sweep.
- **Stop Frequency**  Sets the end value of the frequency sweep.
- **Frequency Span**  Sets the frequency span of the frequency sweep.
- **Number of Frequencies**  Sets the number of data points that the analyzer measures during a sweep. Range: 2 to 20001. (Default is 201).
- **Power Level**  Sets the power level of the source. Learn more.

Power Sweep Sweep Type

Source

- **Start Power**  Sets the beginning value of the power sweep.
- **Stop Power**  Sets the end value of the power sweep.
- **Number Of Powers**  Sets the number of data points that the analyzer measures during a sweep. Range: 2 to 20001. (Default is 201).
- **CW Frequency**  Sets the single frequency where the analyzer remains during the measurement sweep.

Multisweep Sweep Type

Source

- **Start Frequency**  Sets the start frequency of the frequency sweep.
- **Center Frequency**  Sets the center frequency of the frequency sweep.
- **Stop Frequency**  Sets the stop frequency of the frequency sweep.
- **Frequency Span**  Sets the frequency span of the frequency sweep.
- **Frequency Sweep**  Sets the sweep type.
- **Number of Frequencies**  Sets the number of data points that the analyzer measures during a frequency sweep. Range: 2 to 20001. (Default is 201).
- **Start Power**  Sets the beginning value of the power sweep.
- **Stop Power**  Sets the end value of the power sweep.
- **Number of Powers**  Sets the number of data points that the analyzer measures during a power sweep. Range: 2 to 20001. (Default is 201).

Extraction

- **IF Bandwidth**  Sets the IF (Receiver) bandwidth. Learn more.
- **Absolute Power**  The tone power is an absolute power.
• **Relative to Input Power**  The tone power is relative to the input power (dBc).

**Extraction Tone (ET) Level**

The level of the extraction tone must be small enough to ensure a spectrally-linear response, but large enough to ensure that the response is measurable.

A Source Power Cal is performed and both the LSOP (large signal output power) and Extraction tones power levels are adjusted to compensate for loss, external amplifiers, and attenuators.

**Select the method used to set the ET Power Level:**

The goal of both the Absolute and Relative ET Level methods is to set the ET level ~16 dB below the LSOP level while ensuring a spectrally-linear response from the DUT.

- **Relative to the Input Power**
  For example: At the DUT output you know that the DUT gain at the maximum stimulus power is 12 dB. The extraction level is set to -4 dBc (DUT Gain – 16 dB).

- **Absolute Power**
  For example: You know that the DUT gain is 12 dB with the stimulus power at -10 dBm. Then the DUT Max Output power is +2 dBm. The extraction level is set to 16 dB below +2, or -14 dBm (Input Stimulus + DUT Gain – 16 dB).

**Number of Phases**  Sets the number of phase points. At each point, a phase sweep is performed. Several stimulus states are required to extract the unknown parameters. The following is an example of the output power in Polar format with the number of phases set to 21. Note that the oval shown below is due to the non-linearity of the device. The perfect circle shown below is a linear device.
DC

- DC Sources...

**Active Parameter RF Path** tab help

**Power On - all channels** - Check to enable source power for all channels.

**Source**

- **Source Port** Selects the port through which an internal source is available.
- **Source Attenuator** Sets the attenuation of the source.
- **Receiver A Attenuator** Sets the Receiver attenuation.
- **ALC Hardware**
  - **Internal** - ALC leveling. Power level within an attenuator setting is limited to the ALC Range. See **Source Unleveled**.
Open Loop - No ALC and NO Receiver Leveling. Learn more.

- **Receiver Leveling** Turns receiver leveling on/off. This function adjusts the source power until the measured receiver power is equal to the Port Power.

**Extraction**

- **Extraction Port** Selects the port to measure the output of the DUT.
- **Source Attenuator** Sets the attenuation of the source.
- **Receiver C Attenuator** Sets the Receiver attenuation.
- **ALC Hardware**
  - **Internal** - ALC leveling. Power level within an attenuator setting is limited to the ALC Range. See Source Unleveled.
  - **Open Loop** - No ALC and NO Receiver Leveling. Learn more.

- **Receiver Leveling** Turns receiver leveling on/off. This function adjusts the source power until the measured receiver power is equal to the Port Power.

**RF Path Config...**
This tab allows the user to select a subset of the data to be displayed on the screen (frequency, power, phase) by defining the x-axis and a set of fixed values for the other parameters.

**Active**  Selects a trace to be active. A trace must be active before its trace settings can be changed.

**Select all traces**  Check to select all traces.

**X-axis display**  Sets the x-axis sweep type.

  **Frequency**

  - **Fixed Parameters**

    - **Input Power**  Sets a fixed input power level.
    - **Enable interpolation**  Check to enable displayed data to be computed by interpolation.

  **Power**

  - **Fixed Parameters**
- **Frequency** Sets a fixed frequency.
- **Enable interpolation** Check to enable displayed data to be computed by interpolation.

**Phase**

- **Fixed Parameters**
  
  - **Input Power** Sets a fixed input power level.
  
  - **Frequency** Sets a fixed frequency.
  
  - **Enable interpolation** Check to enable displayed data to be computed by interpolation.

**DC**

- **Fixed Parameters**
  
  - **Input Power** Sets a fixed input power level.
  
  - **Enable interpolation** Check to enable displayed data to be computed by interpolation.

- **Name**
  
  - **AO1** Internal DC source #1.
  
  - **AO2** Internal DC source #2.
This dialog is identical to the X-axis tab above.

**Active Hot Parameters help**

**Option S93110A/B Measurement Parameters**

**Note:** In the example below, Port 1 is the Source Port (DUT input) and Port 3 is the Extraction Port (DUT output). Port 3 or Port 2 can be chosen as the output of the DUT.
Option S9311A/B Measurement Parameters
IPwr  Check to measure input power.

OPwr  Check to measure output power.

HotS31  Check to measure Active Gain.

HotS33  Check to measure Active Output Match.

HotS13  Check to measure Reverse Isolation.

HotS11  Check to measure Active Input Match.

Gamma  Check to measure optimized Gamma.

Pmax  Check to measure maximum delivered power.

Xs(3,3), Direct Reflection Coefficient. The fundamental $XS_{33}$ parameter which is used, in combination with $XT_{22}$, to describe the change in $b_2$ as a function of $a_2$, the signal reflected from the load.

Xt(3,3), Direct Reflection Coefficient. The fundamental $XT_{33}$ parameter which is used, in combination with $XS_{22}$ to describe the change in $b_2$ as a function of $a_2$, the signal reflected from the load.
**Xf(3,1),** Output Coefficient. The fundamental $XF_{31}$ parameter.

**DeltaOPwr**  Check to measure the delta between the output wave and output power to Z0 load.

Available for option S9311A/B only (the following traces are not restricted to 50 GHz)

**HotGain**  Check to measure forward gain using linear S-parameters output/input.

**HotMatch**  Check to measure active output match using linear S-parameters.

**Buttons**

**Select All**  Click to select all measurement parameters.

**Clear All**  Click to deselect all measurement parameters.

**Create in New Window**  Check to create a new trace in a new window for the measurement.

**Channel Number**  Select a channel number for the measurement.

---

**Calibrating an Active Parameter Channel**

A calibration can be performed on the Active Parameter Channel using the Cal All Wizard.

**Saving Data**

The data can be saved to a *.csv file with a column for each measurement parameter.
### How to save data

**Using Hardkey/SoftTab/Softkey**
1. Press Save Recall > Save Other > Save Data....
2. Save as type = HotS22 Sweep Data (*.csv)

**Using a mouse**
1. Click File
2. Click Save Data....
3. Save as type = HotS22 Sweep Data (*.csv)
Fast CW Mode (Opt S93118A/B) and other Antenna Features

The following features, used with the PNA-X models and the N5264B, were designed specifically for Antenna applications.

- **Fast CW Mode Features (Opt S93118A/B)**
  - FIFO Buffer and Fast CW
  - FIFO Buffer and Fast Groups
  - FIFO Buffer and Fast Segments

- **Other Useful Antenna Features**
  - Point Averaging
  - Point Sweep
  - Trace Triggering

- **See Also**
  - N5264B
  - Pulsed Measurements
  - Frequency (Security) Blanking
  - External Triggering

### Fast CW Mode Features (Opt S93118A/B)

The following Fast Sweep features allow you to **very quickly** measure and download data to a remote computer.

- **Fast CW, Fast Groups, and Fast CW Segments** all work ONLY with the FIFO Data Buffer.

- These features can be used ONLY with **SCPI or COM commands**. COM is faster than SCPI when using `DataInCompactForm`. Otherwise, SCPI is faster than COM.
The FIFO Data Buffer

The FIFO (First-IN, First-OUT) data buffer is a circular buffer that allows very fast Read-Write access.

- 5 GB FIFO buffer file on the E:\ drive. If the "not enough disk space" error message is displayed, clear all unnecessary files on the E:\ drive.
- You can write to, and simultaneously read from, the FIFO buffer.
- A maximum of 1 million data points can be read for each query.
- REAL / IMAGINARY pairs is the ONLY supported format for the FIFO buffer.
- A preset or instrument state recall will turn off the FIFO buffer collection.
- When more than one measurement is present, data from each measurement is stored in the FIFO buffer in the following order. These measurements are separated into lines for easier reading.

4-port models

- \( R, A, B, C, D, \)
- \( R/A, A/A, B/A, C/A, D/A, \)
- \( R/B, A/B, B/B, C/B, D/B, \)
- \( R/C, A/C, B/C, C/C, D/C, \)
- \( R/D, A/D, B/D, C/D, D/D \)

2-port models

- \( R1, R2, A, B, \)
- \( R1/R1, R2/R1, A/R1, B/R1 \)
- \( R1/R2, R2/R2, A/R2, B/R2 \)
- \( R1/A, R2/A, A/A, B/A \)
- \( R1/B, R2/B, A/B, B/B \)

S-parameters are pre-defined, ratioed-receiver measurements. Learn more. S-parameters are placed in the FIFO in order based on their underlying receivers. For example, S21 is placed into the FIFO in the same manner as B/R1.
Fast CW

In Fast CW mode the VNA display is not updated. There is no background computation or other 'interference' from the VNA computer. Therefore, data is acquired real-time.

The following **requirements** must be met **before** sending the Fast CW command.

- FIFO is ON
- A single channel is being measured. Other channels can be in Hold.
- All measurements are acquired in a single sweep.
- The channel must be in CW mode (start frequency = stop frequency or sweep type = CW Time).

**IMPORTANT - Fast CW and IF Bandwidth setting**

- IF Bandwidth of **10 kHz and lower** - Data is transferred immediately to the FIFO after every acquisition.
- IF Bandwidths **greater than 10 kHz** - Data is transferred to the FIFO in groups. A triggered acquisition is **NOT** placed into the FIFO buffer until either the total number of points is completed, or an intermediate group of points is finished. The number of points within a group differs for each IF Bandwidth setting.

**Notes:**

- See example programs in SCPI and COM.
- Fast CW sets the number of data points, overwriting the standard channel setting.
- 400,000 points/second applies to 600 KHz at a CW frequency with no point triggering. For narrower bandwidths the speed is slower.
- Frequency switching time will reduce the speed. The frequency switching can be anywhere from 50 uS to 1 mS depending on the frequencies. The CW segment itself can go at 400,000 points per second.
- All 5 receivers can do 400,000 point/second at the same time. So the data comes out at 5 times that rate, i.e. 2 Mp/s.
- When exiting Fast CW, the FIFO data buffer is cleared.
- External measurement trigger signals are allowed only on Meas Trigger.
- The Aux 1 and Aux 2 triggers cannot be used per point in FastCW mode.
- Aux 1 and Aux 2 triggers can still be used for external source hardware triggering, but the external sources must be in CW mode.
An error message appears if triggering is sent to the VNA faster than it can respond.

**Fast Groups with FIFO Data Buffer**

With this speed optimization feature, interaction with Windows or other VNA 'overhead' calls are suspended, allowing very fast and predictable measurement timing.

Fast Groups is automatically enabled when the following **requirements** are met:

- FIFO is ON
- A single channel is being measured. Other channels can be in Hold.
- All measurements are acquired in a single sweep.
- Group trigger is enabled with count > 1.

**Notes:**

- Fast CW can **NOT** be used with Fast Groups.
- Fast Groups and Fast CW Segments were designed to be used together, but not required.
- The FIFO Tester example program demonstrates this feature.

**Fast CW Segments with FIFO Buffer**

In this optimization feature, each CW segment (where the start and stop frequency is identical) within a channel is measured at speeds as fast as the Fast CW mode sweep.

Fast CW Segments is automatically enabled when the following **requirements** are met:

- FIFO is ON
- Start and stop frequency of a segment is identical.
- External measurement trigger signals are allowed only on Meas Trigger.
- The Aux 1 and Aux 2 triggers cannot be used per point in Fast CW Segment.
- Aux 1 and Aux 2 triggers can be used for external source hardware triggering.

**Notes:**

- Fast CW can **NOT** be used with Fast CW Segments.
- The sweep can include non-CW segments, but these are not acquired in Fast mode.

- Fast Groups and Fast CW Segments were designed to be used together, but not required.

- The FIFO Tester example program demonstrates this feature.

- In Fast CW Segments, when data is not being acquired in real-time, the following message appears: Caution: Sweep time jitter. Try reducing the number of segments. To avoid this error, reduce the number of segments in the channel.

**Other Antenna Features**

**Point Averaging**

This feature is selected on the Average dialog.

When selected, each data point is measured the specified number of averages before stepping to the next data point. When point trigger is selected, only one trigger is required for each data point regardless of the number of averages.

**Point Sweep**

This feature is selected on the Sweep Setup dialog.

In Point Sweep mode, the VNA measures both the forward and reverse parameters at each frequency point before stepping to the next frequency. The display trace is updated as each data point is measured. Point sweep is the same as stepped sweep mode of the 8510 and 8530.

**Trace Triggering**

This feature is selected under Trigger Mode on the Trigger dialog.

Available ONLY when Point Sweep is selected. Each trigger signal causes two identical measurements to be triggered separately - one trigger signal is required for each measurement. Other trigger mode settings cause two identical parameters to be measured simultaneously.

Trace triggering is NOT permitted when a channel is using a 2 port (or more) S-Parameter calibration.

Programming commands
Features, Requirements, and Limitations

Features

Combines and extends the capabilities of ALL three of these features:

- **Source Phase Control** (Option S9x088A/B) is limited to 2-ports, only 4 receivers - Diff IQ can measure ALL receivers.
- **External sources** (control at the same time as internal sources).
- **FOM** (Frequency Offset Mode - Opt S9x080A)

This allows you to set an internal or external source to any frequency range, any power level, and any phase relative to a defined reference source. Then, measure any receiver over any frequency range independent of the source frequency range(s), with optional match correction. Display the results of any receiver combination using mathematical expressions available with the **Equation Editor** feature.

The magnitude and phase of a controlled source is set relative to a reference source using a pair of receivers (one for the reference source and one for the controlled source), in an iterative loop. The controlled source is adjusted within the loop while measuring the ratio of the two receivers. The loop continues until either the desired magnitude and phase offset is achieved (within user-settable tolerance values), or the maximum number of iterations has occurred.

When controlling an external source, a portion of the output signal must be routed to an internal receiver (usually one of the reference receivers), via a splitter or directional coupler and one of the front- or rear-panel access points. The source can be controlled via any of the available remote interfaces, such as GPIB, USB, or LAN. The 10 MHz frequency reference should be shared between the source and network analyzer.

Requirements

- **Frequency Offset Mode - Opt S9x080A**
- **Available ONLY on 4-port N522xB and N524xB (PNA-X) models.**

Limitations

The following Features are **NOT** Available in a Differential IQ channel:
Differential I/Q Setup Overview

1. Define **frequency ranges** for sources and receivers.
   - Ranges can be fixed or swept frequency.
   - To accomplish necessary measurements, receivers can be tuned to an arbitrary list of frequencies independent of those used for the sources. Define **controlled sources** for frequency, power, and phase relationships to other sources, using ranges from

2. Define **trace parameters**.
   - Parameters can use single receivers or multiple receivers combined with mathematical operators.
   - Parameters can combine receiver measurements made at different frequencies.

3. Define **x-axis** (can be frequency, power, phase, DC, points).

4. **Calibrate** all channels using the Cal All wizard, and if needed for additional direct-receiver response calibrations, the Cal Plan Manager wizard.

How to make Differential I/Q Measurements

**Create a Differential I/Q Channel**

1. On the VNA, press **Meas > S-Param > Meas Class...**

2. Select **Differential I/Q**, then either:
OK delete the existing measurement, or

New Channel to create the measurement in a new channel.

3. A **Differential I/Q measurement** is displayed.

Configure Differential I/Q settings

Using **Hardkey/SoftTab/Softkey**

1. Press **Setup > Main > DIQ Setup...**

Using a mouse

1. Click **Stimulus**.
2. Select **DIQ Setup...**

**Differential I/Q Setup Dialog help**

**Frequency Range** (See **Example configurations**)

Sets the source and receiver frequency range. Each defined frequency range can be measured by all of the VNA receivers. The **Define Parameters** dialog allows you to configure the measurements
to be displayed.

Only Linear sweeps are allowed.

**To make changes**, click the **Range Name** to be changed, then click **Edit** to start the **Frequency Range dialog**.

**New** - Creates a new frequency range.

**Remove** - Deletes a range. This also removes all measurement parameters that use the deleted range.

**Save...** - Saves the measurement setup.

**Load...** - Loads a measurement setup.

**Sources**

**Source Name** - Lists the test ports through which an internal source is available. If an external source has been configured, it will appear at the bottom of the list.

**To make changes**, click the **Source Name** to be changed, then click **Edit** to start the **Source Configuration dialog**.

**Add Source** - Starts the **External Source Configuration** dialog.

**Power ON (All Channels)** - Turns power on to all channels.
To start this dialog, click the **range name** to be changed, then click **Edit**, in the above **Differential IQ Setup dialog**.

**Note:** The Number of Points is always the same for ALL defined frequency ranges. Press **Sweep**, then **Number of Points**

This dialog sets a frequency range for the source and receiver. The frequency range will be measured by ALL of the receivers.

**F1** can NOT be coupled to another range.

**IFBW** - Set the IFBW to be used by the receivers for the specified frequency range.

**Note:** In Diff IQ mode, the IFBW in the VNA status bar may not reflect the channel’s actual IFBW, which can be set independently for each frequency range in the Setup dialog. While the user can modify the status bar IFBW from the status bar, it is not applied to the measurement.

**Procedure**

Either set specific frequencies for the selected range:

- Enter **Start** and **Stop** frequencies or select **Center** and **Span**.
- For a CW frequency, set the **Start = Stop** or **Span = 0**.
Or set frequencies that are based on another already-created range:

- Check **Couple to**, then select the range to base the selected range on.
- Optionally select any of the following:
  - Select a predefined Offset frequency range.
  - **Check Up** to ADD the Offset range to the Couple To range.
  - **Clear Up** to SUBTRACT the Offset range from the Couple To range.
  - Select a **Multiplier** or **Divisor** value.

**How the selected range is calculated**

For the following frequency ranges (as seen in above dialog):

- **Selected (Output) = F3**
- **Couple to = F1**
- **Offset = F2**

The following formula applies for each data point in each range:

\[
F3 = F1 \times \text{Multiplier} / \text{Divisor} + F2
\]

**Note:** The Number of Points is always the same for ALL defined frequency ranges. Press **Sweep**, then **Number of Points**

**Examples**

For **Mixers / Frequency Converters** (See above dialogs)

- F1 = RF or Input Frequencies: Enter Start and Stop Frequency range
- F2 = LO Frequency: Enter CW Frequency (Start = Stop)
- F3 = Couple to F1; Offset = F2

For **Amplifier Harmonics**
F1 = Enter fundamental Start and Stop Frequency range

F2 = Couple to F1; no Offset; Multiplier= 2 (Measures 2nd Harmonic)

F3 = Couple to F1; no Offset; Multiplier= 3 (Measures 3rd Harmonic)

Source Configuration Dialog help

This dialog is started by clicking the Source Name to be changed, then click Edit, in the Differential IQ Setup dialog.

Configures the source for the specified port. You can set or sweep Power, Phase, and perform Match Correction for each source port.

Source State: Choose from the following:

Auto-on - Source power is turned ON at the specified test port when required by the
measurement. This is the most common (default) setting. Auto-on sources are turned OFF when other sources are performing Match Correction sweeps.

**Always On** - Source power is ALWAYS ON, regardless of measurements that are in process. Use this setting to supply source power to a DUT port that always requires power, such as an LO port. This could turn OFF power at another test port. [Learn about internal second source restrictions.](#)

**Off** - Source power is turned off unless needed for match correction at a given port. Use this setting to prevent damage to a sensitive DUT test port.

**Uncontrolled** - (External Sources ONLY). The source state and other settings are NOT changed. Match correction can NOT be performed while uncontrolled.

**Frequency Range** - Selects a frequency range defined in the Differential IQ Setup dialog.

**Ext Source Port** Selects the source port that the external source is routed through. Displayed when an external source is selected as the active port.

**Power**

**Sweep Power** - Check to perform a power sweep.

**Start / Stop Power** - Set both the Start and Stop power levels for power sweep. Set a single (Start) power level for the specified source port.

**Leveling Mode:** Choose from the following:

- **Internal** - ALC leveling loop ONLY; NO Receiver Leveling.
- **Internal R<n>** - Both ALC and Receiver Leveling - where <n> is the reference port (not shown in diagram). To change the reference port, click [Power and Attenuators](#), then Receiver Leveling. [Learn more.](#)
- **Open Loop** - No ALC and NO Receiver Leveling - Used during pulse conditions with the internal source modulators. No leveling is used in setting the source power. The lowest settable power, without attenuation, is limited to -30dBm. The source power level accuracy is very compromised. Use a source power calibration to make the source power somewhat
more accurate.

- **Open Loop R<n>** - No ALC; Receiver Leveling ONLY - where <n> is the reference port. To change the reference port, click **Power and Attenuators**, then **Receiver Leveling**. Learn more.

**Source Attenuator:** Enter source attenuation for the specified port number. Not available for external sources.

**Auto range source attenuator:** Check to allow the analyzer to select the optimum attenuation value to achieve the specified test port power. Learn more.

**Power and Attenuators** - Click to start the **Power and Attenuators** dialog.

**Phase**

**Phase State** - Choose from the following:

- **Off** - Phase is NOT set or controlled.
- **Controlled** - Phase is measured and iterated to within the specified tolerance. Specify the receivers and iteration properties to use to control phase.
- **Open Loop** - Phase and power is set, but receivers are NOT used to measure and iterate the phase or power of the source. Therefore, the setting of phase is not as accurate or stable. Open Loop mode can be used with phase sweep (for example, from 0 to 360 degrees). However, each sweep may not start at 0 degrees. NO settings on the Phase Control Setup dialog are used in Open Loop. **Note:** After selecting Open Loop, set each source to **ON** (not Auto) using the **Power and Attenuators** dialog.

**Sweep Phase** Check to sweep on the specified source port.

**Start / Stop Phase** - Set both the Start and Stop power levels for power sweep. Set a single (Start) power level for the specified source port

**Referenced To** - Select the port to which the controlled phase port is to be referenced. The two internal VNA sources are available ONLY at specific ports. These choices are limited for you. For example on a 4-port PNA-X, the possible port pairings are: 1/3, 1/4, 2/3, or 2/4. Port 1 can NOT be paired with Port 2, and Port 3 can NOT be paired with Port 4. Learn more about these limitations.

**Control Param.** - Select the receivers to be used to measure the phase of the sources.

- The LEFT receiver (a2 in the above image) measures the controlled source.
- The RIGHT receiver (a3 in the above image) measures the reference source.
The swept phase or phase offset will be the difference between these two receivers. Learn more.

Select the receivers based on your application. You are responsible to make sure that your DUT configuration routes the signals of interest to the correct receivers. Otherwise, the phase will not be properly controlled.

**Tolerance**  When consecutive phase measurements of the same data point are within this value of each other, then the phase measurement is considered settled.

**Max Iterations**  Sets the maximum number of background phase measurements to perform in order to achieve settling. If the phase is not sufficiently settled after these measurements, then the closest value is used.

---

**Note:** When both Power and Phase are swept, both are swept SIMULTANEOUSLY in a single sweep.

**Match Correction**

**Note:** Without match correction, receiver-power measurements use simple response calibrations, which do not compensate for the mismatch between the DUT and the match of the test system. This mismatch can appear as ripple in swept-frequency power measurements. With match correction enabled on a given port, an extra sweep is taken at that port to measure the match of the DUT using a 1-port calibration. These data are then used with the port-match data obtained from the Cal All calibration to correct for the mismatch between the DUT and the test system, providing more accurate power measurements.

**Match Correction On**

- Check to perform Match Correction on the specified source port over the specified frequency range. An extra sweep is performed to measure the match term.
- Clear this box if the input of your DUT is well-matched to the analyzer source port.

**Test Receiver** - Select a test receiver to be used for Match Correction. Only logical receiver notation (b1, b2 and so forth) is available. Learn more.

**Reference Receiver** - Select a reference receiver to be used for Match Correction. Only logical receiver notation (a1, a2 and so forth) is available. Learn more.

**Select Frequency Range** - Starts the following dialog.
Select the frequency ranges over which Match Correction is to be performed.

When match-correction is enabled, extra trace parameters are generated in the channel for the match measurements (e.g. S22_F1). The number of match parameters generated depends on which ports enable match correction, and the frequency ranges selected for each port. If these parameters are deleted, or if a set of trace parameters are loaded from an .xml file that doesn’t include the match parameters (loading an xml file overwrites the existing trace definitions), then the match measurements will not be performed, even if the setup dialog includes them. To regenerate the match parameters and enable match-corrected power measurements, match correction must be turned off for a port and then reenabled.

Define a Measurement Parameter

Four 'default' parameters are offered.

In addition, custom parameters can be defined using the **Edit Parameters Dialog**

### How to select and configure Measurement Parameters

#### Using Hardkey/SoftTab/Softkey

1. Press Meas > Main > Other....

#### Using a mouse

1. Click Response
2. Select Meas
3. Select More Measurements...
When match correction is enabled, the firmware automatically generates DUT-reflection parameters Sxx_Fn (e.g. S11_F1, S11_F2 ...) measured with a 1-port calibration. These are the parameters that should be selected for accurate reflection measurements of the DUT. A user-defined Sxx (e.g. UserS11 below) will only be response corrected, and will have considerably more error than the equivalent firmware-generated reflection parameter, which has a full 1-port calibration.

Select one of the following 'default' parameters, or click **Edit Parameters** to show the following **Edit Parameters** dialog.

**Create in New Window** - When checked, the selected measurements are created in a new window.
Parameters

Select a predefined parameter from the list.

**Parameter Name** - Change the 'default' name. Click **Edit Name** to start the virtual keyboard.

*Note:* Do not use underscores in the parameter name. For example, b2_f1 cannot be used as a parameter name. However, b2f1 is a valid parameter name.

To edit / create a parameter:

**Receiver** - Select a receiver for which to plot measurement results.

**Frequency** - Select the frequency range over which the results will be plotted.

***(Operator)*** - Select an operator when combining multiple receivers. For example, when calculating differential or common mode parameters.

**Buttons**

**New** - Click to create a parameter.

**Remove** - Click to delete the selected parameter.

**Save** - Click to store the parameter to a *.diq file for later recall.

**Load** - Click to recall a parameter that you previously defined and saved.

The following are the contents from an example *.diq file that contains the above parameters.

The file can be created using the above dialog, or edited directly using the format shown below.
<Source_Phase_Control>
  <ParameterList>

IsUpConvert="true" Multiplier="1" Divisor="1"/>

<Range4 Start="1300000000.000000" Stop="1300000000.000000" IFBW="10000.000000"
  IsCoupling="true" CoupleId="2" Offset="1"
  IsUpConvert="false" Multiplier="1" Divisor="1"/>

</FrequencyRanges>
</Source_Phase_Control>

How to Select X-Axis

Using Hardkey/SoftTab/Softkey

1. Press **Sweep > Main > X-Axis Type...**

Using a mouse

1. Click **Stimulus**
2. Select **Sweep**
3. Select **X-axis Type...**

Select X-Axis Dialog help

Select the domain to display on the X-axis of the window.

Markers will be annotated and data files are saved using these choices.

Choose from the following:
Calibrating a Differential IQ Channel

Calibration of the Differential IQ Channel is performed using the **Cal All Calibration Wizard**.

Cal All should be performed with all of the front panel jumpers in place and all of the path switches in the normal configuration. After the cal has been performed, the path switches can be set to the rear panel position if external sources are routed from the rear panel to the test ports.

This calibration appears as an S-parameter calibration in the Cal All Wizard.

**Direct Access Receiver Calibration**

When all four test ports are being used, but at least one port uses ONLY the source and its reference receiver, you can use the test port receiver for that port accessed through the front-panel jumper ports.

This measurement is calibrated by first performing the Cal All Calibration.

Then use the Cal Plane Manager - Direct Receiver Calibration to remove the effects of the transmission line that is used to connect the DUT to the receiver through the front-panel jumper port. See the detailed procedure.

**Note:** Only corrected scalar magnitude measurements are possible at the direct-access receiver. The phase information from the Cal All calibration is preserved in the Cal Set and is NOT modified by the Direct Access Receiver Cal.
FCA includes both Scalar (SMC) and Vector (VMC) measurements and calibrations.

In this topic:

Other Application topics

FCA Options Explained

• Option S93083A/B provides FCA which includes Scalar Mixer (SMC) and Vector Mixer (VMC) Measurements.
• Option S93082A/B provides ONLY SMC measurements. This is the ONLY FCA option that is allowed on the N5230C.
• Option S93084A/B provides Embedded LO measurements. This option requires one of the Converter Applications.
• See all PNA-X Options and Configurations.

Requirements and Limitations

The following VNA features are NOT available with FCA:

- Analog Sweep (Stepped sweep mode only)
- Log frequency sweeps
- ECal User Characterization (can NOT be created in FCA channel)
- Time Domain
- Balanced measurements
- Port extensions
- Some Fixturing Features
- External Test Set Control (Option S93551A/B)
- PMAR (Power Meter As Receiver)
How to make SMC or VMC Measurements

The following is an overview of how to make an FCA measurement:

1. DECIDE to use either a SMC or VMC measurement. See a comparison of these two measurement types.
2. CREATE an SMC or VMC Measurement.
3. SETUP the measurements.
4. CALIBRATE your SMC or VMC measurement.

Create an SMC or VMC Measurement

1. Press Setup > Main > Meas Class...
2. Select SMC or VMC, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.
3. The default SMC or VMC measurement is displayed.
4. See SMC measurements or VMC measurements to learn about the parameters that are offered in each.

How to make SMC or VMC settings

Using Hardkey /SoftTab /Softkey

1. Press Freq > Main > SMC Setup... or VMC Setup... .

Using a mouse

1. Click Stimulus
2. Select Frequency
3. Select SMC or VMC Frequency...

Valid Mixer Configuration / Sweep Type Combinations
Configuring the SMC and VMC Setup dialog can be challenging at first. RED messages like this one appear at the bottom of the Setup dialog to notify you of an invalid setup.

At least one range (Input, LO, or Output) MUST be Fixed.

The following are the **Valid Mixer Configurations**:

<table>
<thead>
<tr>
<th>Sweep Type</th>
<th>Input</th>
<th>LO</th>
<th>Output</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

**Tips**

Although you will soon become comfortable navigating these tabs, at first it may be best to complete the dialog in the following order:

1. For 2-stage mixers, select Mixer Setup settings.
2. Select Sweep tab settings.
3. Select Mixer Frequency settings.
4. Select Power settings.
5. Select Mixer (LO) Power settings.

The following FCA settings are common to VMC and SMC:
Sweep Tab - SMC and VMC dialog box help

**Sweep Type**

- **Linear**  Sweep frequency. Measurements are displayed on a standard grid with ten equal horizontal divisions. Learn how to select the range to display on the X-Axis.

- **CW Time**  All ranges are set to a Fixed (CW) frequency, and the data is displayed versus time.

- **Segment Sweep**  Sweep user-defined segments. Learn more.

- **Power**  Sweep Input or LO power.

**X-axis Point Spacing**  (Available only with Segment Sweep) - Learn about this feature

**Avoid Spurs**  - Learn about this feature.

**Reversed Port 2 Coupler**  (SMC ONLY)  Check when making SMC measurements with the Port 2 coupler reversed. Learn how. Do this to increase power at low frequencies. Checking this box has the following effects:

- The measurement is faster because Reduce IFBW is no longer performed on SC21 measurements.

- The SMC Calibration no longer attempts to level the Port 2 power (it is not possible to level the power through the coupler at those low frequencies). This keeps the VNA from producing "source unleveled" errors on Port 2.

**Number of Points**  Learn about this feature.

**IF Bandwidth**  Learn about this feature.

**Phase Reference Point**  (SMC ONLY)  Learn about this feature.

Learn about these buttons.
### Power Tab - SMC and VMC dialog box help

**Note:** Set LO Power on the Mixer (LO) Power tab.

Configures Input and Output power settings for an FCA measurement. Use the Mixer Power tab to set LO power.

**Power ON (All channels)**  Check to turn RF Power ON or clear to turn power OFF for all channels.

**Port Powers Coupled**  Check to set the same power level at the DUT Input and Output ports. The LO power is NOT coupled. Clear to set power levels independently for each test port. Uncouple power, for example, to apply more power in the reverse direction than in the forward direction. Learn more about Setting Independent Port Power.

**DUT Input / Output Port**

Select the VNA port that is connected to the DUT Input and Output. For VMC, the DUT input must always be connected to VNA port 1 because of the need for a reference mixer on port 1.

**Power Level**  Set the power level to the DUT Input port. To set power at the Output port, clear the **Port Powers Coupled** checkbox.

**Source Attenuator Auto**  Check to automatically select the correct attenuation to achieve the specified input power. Clear, then select attenuator setting that is used achieve the specified Power Level. Learn more about Source Attenuation.

All VNA channels in continuous sweep must have the same attenuation value. Learn more.
**Receiver Attenuator**  Specifies the receiver attenuator setting for the DUT port.

**Source Leveling**  Choose from: **Internal** (normal operation), **Open Loop** (used only for Wideband Pulse measurements), or **Receiver - R1** for Receiver Leveling.

**DUT Input and Output Port Power Sweep**

Available when Power (sweep) is selected on the Sweep tab.

**Input Start** and **Stop Power**  To set Start and Stop power at the Output port, clear the **Port Powers Coupled** checkbox.

**Note:** If your DUT requires more input power than this setting allows below 3.2 GHz, use the PNA-X **Hi-power mode**, available from the RF Path Configuration dialog. The disadvantage to this is higher harmonic content.

**Power Points**  Number of power points to measure.

**Power Step (Size)**  Calculated value from current Start, Stop, and Points settings. This setting can NOT be changed directly.

**Path Configuration**  click to launch the RF Path Configuration dialog.

The following tabs are shared with all Mixer / Converter Applications:

- Mixer Frequency tab
- Mixer (LO) Power tab
- Mixer Setup tab
Mixer Frequency tab - SMC and VMC Setup - dialog box help

Learn about this dialog

Mixer Setup tab - SMC and VMC Setup - dialog box help

Learn about this dialog
Learn about this dialog

**FCA Segment Sweep**

The following settings appear on the Mixer Frequency tab when **Segment Sweep** is selected on the Sweep tab.

**Mixer Frequency tab - Segment Sweep - SMC and VMC dialog box help**

**How to configure a segment using the GUI:**

1. Click **Add**. Click Delete to remove a segment and renumber all subsequent segments.

2. State is **ON** by default. Click **OFF** and that segment will not be included in the sweep.
3. Configure **Frequency settings** for Input, LO, and Output ranges.

- For each segment, the same sweep requirements apply as a standard (non-segment) sweep. For example, at least one range MUST be Fixed (Start = Stop frequencies).
- The Input, Output, and LO frequencies of segments ARE allowed to overlap other segments.
- All segments must sweep in either the forward (Start<Stop) or reverse (Start>Stop) directions. Mixed sweep directions are NOT allowed.
- The following settings can be set independently for each segment:
  - **Number of Points** - Total number of points for all segments is limited to the Max allowed by the VNA.
  - IF Bandwidth
  - **Port Powers**: (Input, Output, LO 1, LO2). These settings override the settings on the Power tab.

- The following settings apply to ALL segments:
  - Number of Converter/Mixer Stages (1 or 2).
  - LO Source Selections
  - All Input and LO Multipliers and Dividers
  - Source and Receiver Attenuator Settings
  - Source Leveling
  - Avoid Spurs
  - Nominal Incident Power (SMC only)
  - X-Axis Display (Input, LO1, LO2, Output) There must be at least two data points for this setting to be available.
  - X-Axis Point Spacing (vs Normal point spacing).
  - SMC + Phase

- Mixer Segment sweep data can be saved to a *.S2PX file (NOT *.S2P).
- Mixer Segment setup information is saved to a *.MXRX or *.CSV file. Learn more.

**How to add multiple segments using the GUI and Excel *.csv file:**
Start with the GUI to set up mixer settings and to create the first segment then save it as a *.csv file. The *.csv file will then be opened in Excel and the additional segments will be entered. Learn more.

1. Click **Add**.

2. State is **ON** by default. Click **OFF** and that segment will not be included in the sweep.

3. Configure **Frequency settings** for Input, LO, and Output ranges.

4. Click on the **Save...** button.

5. Select **CSV (Comma delimited) (*.csv)** to save the settings and first segment to a *.csv file.

6. Open the *.csv file in Excel.

7. Highlight the segment row then copy it.

8. Paste the copied segment row to add the desired number of segments into the Excel file.

9. Modify the settings for each added segment as necessary. The following is an example showing 3 segments:

10. Save the *.csv file.

11. In the GUI, load this *.csv file.
Learn about these buttons

Apply and Interpolate FCA Cal Sets

In general, when a Cal Set covers a wider frequency range than the channel, the VNA will offer to interpolate the Cal Set when it is applied. Learn more. However, with FCA measurements the LO frequency range may also be considered.

- VMC measurements ALWAYS CONSIDER the LO frequency range and performs interpolation if possible. If the LO frequency range of the measurement is NOT within the LO frequency range of the Cal Set, than the Cal Set can NOT be applied.

- SMC measurements ALWAYS IGNORE the LO frequency range. Therefore, if the Input and Output frequency ranges of the measurements are within those of the Cal Set, then the Cal Set is interpolated if necessary and applied. For example, this would allow you to perform ONE SMC calibration with Input range = the VNA frequency span, LO at 0 Hz, and Output range + the VNA frequency span. This Cal Set could be applied to ALL SMC measurements. Learn more about applying SMC Cal Sets.

These same general concepts apply to segment sweeps. However, if ALL applicable frequency ranges (SMC: Input and Output and VMC: Input, Output, and LO) are NOT within those ranges of the measurement for ONE segment, then the Cal Set is NOT applied for ANY segment.
Select X-axis Display for FCA Measurements

Click **Sweep > Main > X-Axis Type**, then select the desired type.

When **Sweep Type = Linear**, you can choose to show the frequency range of any of the swept parameters on the X-axis.

For example, the following image shows an SMC Fixed Output response with the **Input frequency range** on the X-axis:

- **Output**: 100 MHz (data trace)
- **Input**: 2 GHz to 23 GHz (X-axis)
- **LO**: 1.9 GHz to 22.9 GHz (not shown)

Marker annotation shows Output power at Input frequency.

Save Trace Data

You can save your FCA measurement data in several standard formats.

Click **Save Recall > Save Other > Save Data...**.

The following shows how CSV and SNP files are saved.

Mixer Trace Data

When you select **Mixer Trace Data**, the FCA data is saved to a CSV file in the following format:
# MIXER TRACE FILE, A.01.00

SegIndex, InputFreq, OutputFreq, LO1Freq, InputPower, LO1Power, SC21 Mag (dB), SC21 Phase (Deg)

**SNP Format**

Each record contains 1 stimulus value and 4 parameters (total of 9 values) as follows:

Stim Real($p_1$) Imag($p_1$) Real($p_2$) Imag($p_2$) Real($p_3$) Imag($p_3$) Real($p_4$) Imag($p_4$)

where $p_X$ is the parameter depending on measurement type:

<table>
<thead>
<tr>
<th>Measurement Type</th>
<th>$p_1$</th>
<th>$p_2$</th>
<th>$p_3$</th>
<th>$p_4$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scalar</td>
<td>S11</td>
<td>SC21 (FWD)</td>
<td>SC12 (REV)</td>
<td>S22</td>
</tr>
<tr>
<td>Vector</td>
<td>S11</td>
<td>VC21</td>
<td>VC12</td>
<td>S22</td>
</tr>
<tr>
<td>Mixer Characterization</td>
<td>Directivity</td>
<td>Source Match</td>
<td>Reflection Tracking</td>
<td>M21</td>
</tr>
</tbody>
</table>

- If correction is OFF, data is only saved for the active parameter. Zeros are saved for all other parameters.
- If correction is ON, data is saved for all of the parameters.

All files contain the following Header Information: Brackets [ ] contain parameters.

**Avoid Spurs**

On the Mixer Setup dialog box, check **Avoid Spurs**
The Avoid Spurs feature of the Frequency Converter Application attempts to prevent unwanted mixing products from appearing on the VNA screen. The Avoid Spurs feature does not significantly impact measurement speed.

**Note:** The Avoid Spurs feature is OFF by default for FCA calibrations. For highest accuracy, make measurements with the Avoid Spurs feature at the same state (ON or OFF) as was used when calibrating.

**Description**

A spur, or spurious signal, is a term used to describe the unwanted product of two signals mixing together. When you configure the mixer setup dialog box for a desired Output, the VNA computes the frequencies of potential unwanted signals. By manipulating internal VNA hardware, these signals are avoided and do not appear on the VNA display. This means you do not need to use external filters to prevent spurious signals from appearing on the VNA display.

The time required for the VNA to compute the frequencies of unwanted spurious signals MAY be noticeable depending on the number of data points in your measurement. However, once computed, the time required for the VNA to avoid the spurs is usually insignificant.

**Limitations**

The Avoid Spurs utility cannot avoid every spur. However, when there is a choice of spurs to avoid, it will avoid the largest spur.

**The Computation of Avoided Spurs**

The Avoid Spur computer avoids the following spurs:

- LO, and its interaction with internal VNA components, and 16 of its harmonics.
- Input frequencies and 16 of its harmonics.
- Undesired Image frequencies (Sum or Difference) and 16 of its harmonics.
Scalar Mixer/Converter Measurements (SMC)

SMC Setup and Calibration is very similar to VMC. See FCA Overview to learn about the features that are common to these two applications.

The following information is unique to SMC:

- SMC Hardware Setup
- Create an SMC Measurement
- SMC Parameters Offered
- The SMC Mixer Setup dialog
- Speed Up SMC Measurements
  - Use Nominal Incident Power
  - Apply a Cal Set or SMC Cal Type
    - Reverse Port 2 Coupler below 55 MHz (separate topic)
- SMC Calibration
- SMC + Phase (separate topic)

How to make an SMC Fixed Output Measurement
SMC with a Booster Amp
Programming Commands

SMC Hardware Setup
SMC requires a **power meter/sensor, two sources, and a Cal Kit or ECal module**

- Your DUT can be connected to any VNA ports. Learn more.
- When using a PNA-X with an Internal Second Source, the external source is NOT necessary. Learn which VNA ports can be used for the LO.
- For 2-port VNAs, connect **External Source** to the VNA GPIB Controller port. Learn how to Configure an External Source.
- Connect the **10 MHz reference signal** of an external source to the VNA. This is especially important with SMC + Phase measurements.
Use either a GPIB power meter or USB power sensor.

**How to configure two power sensors** to cover the SMC measurement frequency range.

Using a dual channel power meter, with both sensors connected:

1. At the SMC Select DUT Connectors dialog, click **Source Cal Settings**
2. At **Source Calibration Settings** dialog, click **Power Meter Config**
3. At **Power Meter Settings** dialog, click **Sensors**
4. At **Power Sensor Settings** dialog, clear the "Use this sensor only..." checkbox for both sensors.
5. Then enter the Min and Max Frequencies for both sensors.

During the SMC Cal, you will be prompted to connect each sensor at the appropriate time.

**Create an SMC Measurement**

1. Press **Setup > Main > Meas Class....**
2. Select **SMC**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.
3. An SC21 measurement is displayed.

**SMC Parameters Offered**

To select additional parameters to display, click **Trace**, then click on a new trace, then select a parameter from the list.
**Important Note:** Connecting your DUT to the VNA:

**RF** and **IF** terminology is NOT used in FCA because the VNA does not know how the DUT is labeled or how it will be used. Instead, the general terms **INPUT** and **OUTPUT** are used.

- **INPUT** - The DUT port being stimulated with frequencies before conversion.
- **OUTPUT** - The DUT port outputting converted frequencies.

**INPUT** and **OUTPUT** Frequencies are specified using the **Mixer Setup dialog box**.

The DUT input and output can be connected to any VNA ports.

**Note:** Although there are MANY configuration possibilities, the following images and descriptions show ONLY a DUT connected to VNA ports 1 and 2.

Legend:

- **Black** are ratioed measurements (test port/reference receiver).
- **Green** are unratioed measurements (either a test port OR reference receiver).

<table>
<thead>
<tr>
<th>DUT <strong>Input</strong> to VNA <strong>port 1</strong></th>
<th>DUT <strong>Input</strong> to VNA <strong>port 2</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>DUT <strong>Output</strong> to VNA <strong>port 2</strong></td>
<td>DUT <strong>Output</strong> to VNA <strong>port 1</strong></td>
</tr>
</tbody>
</table>

**Ratioed**

- **SC21 (Conversion Loss)** Stimulus at Input, response at Output (B/R1).
- **SC12 (Reverse Isolation)** Stimulus at Output, response at Input (A/R2)

**Ratioed**

- **SC12 (Conversion Loss)** Stimulus at Input, response at Output (A/R2)
- **SC21 (Reverse Isolation)** Stimulus at Output, response at Input (B/R1)
### S11 (Input match)
Stimulus and response at Input (A/R1)

### S11 (Output match)
Stimulus and response at Output (A/R1)

### S22 (Output match)
Stimulus and response at Output (B/R2)

### S22 (Input match)
Stimulus and response at Input (B/R2)

#### Unratioed
Absolute test port receiver measurements. The receiver is automatically selected depending on the DUT configuration.

- **IPwr** (Incident Power) - stimulus and response at Input.
- **RevIPwr** (Reverse Incident Power) - stimulus and response at Output.
- **OPwr** (Output Power) - stimulus at Input, response at Output.
- **RevOPwr** (Reverse Output Power) - stimulus at Output, response at Input.

#### Internal ADC Stimulus / Response Measurements (AI).

AI(x,y) where:

- **x**=ADC to use. Choose 1 or 2.
- **y**=port number at which ADC is available

Learn more about [ADC Measurements](#).

#### Externally-configured DC Measurements

---

### SMC Mixer Setup

#### How to start the SMC Mixer Setup dialog

**Using Hardkey/SoftTab/Softkey**

1. Press **Sweep > Main > SMC Setup... > Mixer Setup** tab.

**Using a mouse**

1. Click **Stimulus**
2. Select **Sweep**
3. Select **SMC Setup...**
4. Select **Mixer Setup**

---

The following SMC Mixer Setup dialog tabs are presented:
- Sweep Tab (shared with VMC)
- Power Tab (shared with VMC)
- Mixer Freq Tab (shared with all converter apps)
- Mixer Power Tab (shared with all converter apps)
- Mixer Setup Tab (shared with all converter apps)

**Speed Up SMC Measurements**

Using default SMC settings, any calibrated SMC measurement requires four sweeps. However, you can reduce the number of sweeps required by selecting one or more of the following settings.

- Use Nominal Incident Power
- Apply Cal Set or Cal Type
- To speed up a Swept LO measurement when using an external source for the LO, use Hardware List (BNC) Trigger setting. Learn more.
- Reverse Port 2 Coupler below 55 MHz (separate topic)

**Use Nominal Incident Power**

Click **Response**, then **Measure**, then **Use Nominal Incident Power**

Each data sweep of a fully corrected SMC transmission measurement actually requires FOUR data sweeps. When you clear **Use Nominal Incident Power**, the reference receiver (R1 or R2) does NOT measure incident power. Instead, the incident power is assumed to be at the level that was set with the Source Power Calibration that is done as part of every SMC measurement. The degradation in accuracy is very negligible if the input or output of your DUT is well-matched.

This selection eliminates sweeps ONLY when both Include Input Match AND Include Output Match is cleared on the Cal Type dialog. Learn more.

**Apply a Cal Set or SMC Cal Type**

You can create an FCA measurement and apply an existing Cal Set as you can with any VNA measurement. Learn about Cal Sets. In addition, from a Cal Set, you can apply a specific SMC Cal Type to an existing SMC measurement.
How to apply an SMC Cal Type

1. Create an SMC measurement
2. Calibrate or apply an existing SMC Cal Set, then...

Using Hardkey/SoftTab/Softkey

1. Press Cal > Main > Correction Methods....

Correction Method dialog box help

By default, each SMC calibration requires FOUR sweeps. Clearing boxes will eliminate sweeps and speed up your SMC measurements. The difference in speed is most noticeable when making fixed input or fixed output measurements with an external LO source.

Include input match correction Check to perform a sweep to measure and correct for INPUT match. Clear this box if the input of your mixer is well-matched to the VNA, or if your setup does not permit a valid S11 measurement.

Include output match correction Check to perform a sweep to measure and correct for OUTPUT
match. Clear this box if the output of your mixer is well-matched to the VNA, or if your setup does not permit a valid S22 measurement.

**Include SC12 Sweep** Check to perform a reverse sweep to measure SC12.

- When checked (default setting), a calibrated SMC measurement sweeps in both forward (SC21) and reverse (SC12) directions.
- Clear this checkbox to eliminate sweeps in the reverse direction. This means that the following measurements will NOT be corrected: SC12, RevOPwr, RevIPwr.

**Corrected Parameters** Lists the parameters that can be corrected given the boxes that are currently checked. These parameters may not be currently measured.

**Calibration Type** Shows the type of SMC Cal that will be applied given the boxes that are currently checked.

Learn about **Use Nominal Incident Power**

**How many sweeps can be eliminated?**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Parameters</th>
<th>Learn about parameter abbreviations</th>
<th># of sweeps</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL checked and clear Use Nominal Incident Power</td>
<td>IPwr, OPwr, RevIPwr, RevOPwr, SC21, SC12, S11, S224 Total</td>
<td></td>
<td>Total</td>
</tr>
<tr>
<td>Perform this action...</td>
<td>to REMOVE these parameters...</td>
<td>and these sweeps</td>
<td></td>
</tr>
<tr>
<td>Clear &quot;Include SC12&quot;</td>
<td>Remove RevIPwr, RevOPwr, SC12</td>
<td>Removes 1</td>
<td></td>
</tr>
<tr>
<td>Clear &quot;Include OUTPUT match&quot;</td>
<td>Remove S22</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Clear &quot;Include INPUT match&quot;</td>
<td>Remove S11</td>
<td>Removes 1 when Nominal is checked*</td>
<td></td>
</tr>
<tr>
<td>Check &quot;Use Nominal Incident Power&quot;</td>
<td>Remove IPwr, RevIPwr</td>
<td>May remove up to 2*</td>
<td></td>
</tr>
<tr>
<td>ALL cleared and check Nominal Incident Power</td>
<td>OPwr, SC21</td>
<td></td>
<td>1 Total</td>
</tr>
</tbody>
</table>

*S11 shares a sweep with IPwr and S22 shares a sweep with RevIPwr. Therefore, when **Include Input Match** or **Include Output Match** is checked, then checking Nominal incident power does nothing.

**VMC measurement** sweeps can NOT be eliminated.
SMC Calibration Overview

The SMC Calibration Wizard guides you through this process.

When applying a Phase Reference cal set, step 1 (power cal) is NOT performed.

1. Connect a power meter / sensor to VNA Port 1. At each step of the input and output frequency, the VNA measures:
   - input match of the power sensor
   - source power of the VNA

2. Perform two Full 2-port calibrations: one over the INPUT frequencies and one over the OUTPUT frequencies of the DUT. (If your DUT is a linear device, the calibration uses only the INPUT frequency range.) Use either a mechanical calibration kit or an ECal module.

For Mixers / Converters with High-output Power

The Unknown Thru method is NOT valid when there is over 40 dB of combined loss in the Unknown Thru and calibration path. In this case, the following calibration and correction method is recommended.

- On the Cal Wizard Modify Frequency page, select Defined Thru or Flush Thru as the Thru method. When using an ECal module, also on the Modify Frequency page, disable (clear) Do Orientation due to very low power.
- After calibration, on the Correction Method dialog, CLEAR the Include output match correction and Include SC12 Sweep check boxes. Check ONLY Include input match correction.
- To learn more about High-power measurements, see our App Notes.

SMC Cal Wizard

The following dialog boxes are presented during an SMC Calibration.

Indented steps are optional.

- Calibration Setup
  - Waveguide/In-fixture/On-Wafer Setup
- Select DUT Connectors and Cal Kits
- Modify Frequency Cal
- Specify how the ECal module is connected
- Power Cal Settings
- SMC Cal Steps
- Calibration Completed
- Specify Adapter Delay

**How to Perform a SMC Calibration**

1. Create an SMC measurement, then...

**Using Hardkey/SoftTab/Softkey**

1. Press Cal > Main > Smart Cal....

**Using a mouse**

1. Click Response
2. Select Cal
3. Select Smart Cal...

**SMC Calibration Setup dialog box help**

Allows you to review and change the settings for your SMC calibration.

**Note:** With release A.09.90 and before, checking both 'Independent power cals' AND 'Use Phase Reference Calset' would generate an error after performing the calibration. With releases AFTER A.09.90, the two settings are compatible.

**Waveguide/In-fixture/On-Wafer Setup** Click Next to launch the following Setup dialog box.
Independent power cals for input and output ports (no thru)  Check if a Thru standard is NOT available. During the power cal, you will be prompted to connect the power sensor to the Input, then the Output port.

**Additional Power Cal Steps**

**Enable LO1 / LO2 Power Cal**  Check when LO1 / LO2 is controlled (on the Mixer Setup tab) to perform a Power Cal on the LO source(s).

**Phase Correction**

**Enable Phase Correction**  Check to enable Phase measurements.

Choose one of the following methods to specify the delay through the characterized mixer. With the first two methods, the phase delay through a Calibration Mixer is measured and compared to the known delay, either entered, or stored in an *.S2PX file.

- **Use Known Mixer Delay**  Enter the fixed, known, delay through the calibration mixer.
- **Use Characterized Mixer**  Select, then browse to the *.S2P file that characterizes the calibration mixer. Use an *.S2PX file when making segmented SMC + Phase measurements. Learn more. Use either of the following two methods to characterize the Cal Mixer over the SMC measurement frequency range:
  
  1. Use the Mixer Characterization Wizard. (Click Response, then Cal, then Mixer Characterization Wizard.) The Cal Mixer has the same requirements as the VMC Cal Mixer. Learn more.

  2. In a calibrated VMC channel, measure the group delay of the calibration mixer, then save to an *.S2P or *.S2PX file. However, a characterized mixer is required to calibrate the VMC channel.

- **Use Phase Reference Calset**  Select, then browse to the Phase Reference Calset that covers the frequency range of the current measurement. Learn more about SMC with a Phase Reference Calibration.

**Waveguide/In-fixture/On-Wafer Setup** dialog box help
This dialog box appears ONLY if you checked the Waveguide/In-fixture/On-Wafer Setup box in the previous Cal Setup dialog.

Allows you to embed or de-embed circuit networks on the input and output of your mixer under test.

For Network1 (Input) and Network2 (Output) select Embed, De-embed, or None.

**Browse** Click to navigate to the .S2P file that models the network to embed or de-embed.

**Reverse port positions for input/output** Check to cause the Fixture/Adapter to be configured with Port 2 connected to the VNA and Port 1 to be connected to the DUT. The image in the dialog is updated to reflect that change.

**Enable Extrapolation** Check (default setting) to apply a simple extrapolation when the S2P file has a narrower frequency range than the channel. The values for the first and last data points are extended in either direction to cover the frequency range of the measurement. A warning message is also displayed when extrapolation is necessary.

**To Embed or De-embed**

- When you have a 2 port network that needs to be connected between the Cal reference plane and the DUT during the measurement, but it is NOT present during the calibration, then that network has to be **De-Embedded** from the port in question during the calibration. In other words, De-Embedding in FCA calibration extends the calibration reference plane to include the two port network.

- When you have a 2 port network that is included as part of the calibration reference plane but has to be disconnected during the measurement, then that 2-port network has to be **Embedded** for the port in question during the calibration. In other words, Embedding in FCA calibration retracts the calibration reference plane to exclude the two port network during the measurement.

**Notes**

- Interpolation is performed when more frequencies are included in the file than in the channel, and the data points do not exactly match those of the measurement.
Select DUT Connectors and Cal Kits dialog box help

Allows you to specify the connector type and Cal Kit for each DUT port.

**Port n**  For each listed VNA port, specify the DUT connector type and gender, and the Cal Kit to use.

**Note:** If your DUT connectors are:

- **Waveguide** Change the system impedance to 1 ohm before performing a calibration. See Setting System Impedance.

- **Not listed** (male and female) Select **Type A** as the connector type. Type A requires a calibration kit file containing the electrical properties of the standards used for calibration (see Calibration kits).

- **Unspecified** (like a packaged device) Select **Type B** as the connector type. Type B requires a calibration kit file containing the electrical properties of the standards used for calibration (see Calibration kits).

**Modify Cal** Check, then click **Next**, to start the Modify Frequency Cal dialog.

**Source Cal Settings** Click to start the Source Cal Settings dialog.
Modify Frequency Cal dialog box help

This dialog appears only when **Modify Cal** is checked on the previous dialog.

**Thru Cal Method**  For each Thru connection, choose the Thru method. Learn more about these choices.

**Cal Type/Stds**  Click to start the Modify Calibration Selections dialog box.

**The following selections are available ONLY if using an ECal module.**

**Do orientation**  When this box is checked (default) the VNA senses the ECal model and direction in which the ECal module port is connected to the VNA ports. If power to the ECal module is too low, it will appear as if there is no ECal module connected. If you use low power and are having this problem, clear this check box to provide the orientation manually. Orientation occurs first at the middle of the frequency range that you are calibrating. If a signal is not detected, it tries again at the lowest frequency in the range.

See note about calibrating for high-output mixer/converters using an ECal module.

**View/Detect ECal Characterizations**  Appears only if an ECal module is selected for use. Click to invoke the View ECal Modules and Characterizations dialog box. Displays a list of ECal modules that are connected to the VNA.
**Power Cal Settings dialog box help**

**Note:** A Use Power Table checkbox (not shown) is available when a mmWave SMC measurement is active. [Learn more.](#)

**Power Cal at:** Select the source port for which a Power Calibration will be performed. The source and receiver correction will be transferred to all other sources and receivers involved in the S-parameter measurements.

**Use Multiple Sensors** (NOT available with mmWave SMC measurements.) Check this box when you want to use more than ONE power sensor to cover the measurement frequency range. The dialog is replaced with the Multiple Sensors dialog (see following image). When "Use Multiple Sensors" is cleared (default setting), connect only ONE sensor to the VNA.

**Power Meter Settings** Click to start the standard Power Meter Settings dialog.

**De-embed (power sensor) adapter** When the power sensor connector is NOT the same type and gender as the DUT connector for the specified port, then for optimum accuracy, extra cal steps are required to measure and correct for the adapter that is used to connect the power sensor to the reference plane.

- Clear this box to NOT compensate for the added adapter.

- Check this box to perform extra calibration steps to measure and correct for the adapter.

Then select the **Power Sensor Connector** type and gender of the power sensor. "Ignored" does NOT compensate for the added adapter, just as if the checkbox were cleared.

- When this connector matches the DUT connector for the same port, then the VNA assumes that there is no adapter. Extra cal steps are NOT required and the Cal Kit selection is not available.

- Otherwise, select the **Cal Kit** to be used to calibrate at the adapter.

See **Accuracy Settings** below.
**Specify how the ECal module is connected** dialog box help

![Specify how the ECal module is connected](image)

This dialog box appears when the **Do orientation** checkbox in the previous **Modify Frequency** dialog box is cleared.

Click the ECal Port that is connected to each VNA port.

---

**SMC Calibration Steps** dialog box help

![SMC Calibration Steps](image)

**Power Level** at which to perform the Power Cal.

It is usually best to set power level to 0 dBm at the power sensor because the power sensor is calibrated at that level. Lower power levels will yield a slower and noisier calibration.

If an external component is used between the PNA-X test port and the calibration reference plane, then adjust the power level so that the power at the sensor is about 0 dBm if possible.

The current source attenuation value is shown on the dialog.

**LO Power Cal (Optional)** When enabled, perform a Source Power Cal at the DUT LO connector. An LO must already be selected. Learn how. The power level of the LO source calibration is set on the **(LO) Power Tab**.
Calibration Completed dialog box help

Finish  Save to the channel's calibration register.

Save As User Cal Set  Starts the Save as User Cal Set dialog box AND save to the channel's calibration register.

Cancel  Calibration is NOT applied or saved.

Learn about Calibration Registers.

Learn about User Cal Sets

Specify delay dialog box help

This dialog appears ONLY when Adapter Removal or Unknown Thru calibrations are performed.

The following values were estimated from the measurement. Most of the time, they are adequate. However, for CW sweep or frequency sweep with large step sizes, the accuracy of the values may be improved.

Adapter delay  To improve this value, measure and record the delay of the adapter with a dense step size. Enter that value here. The required precision value is the accuracy that is required to characterize the delay value.

Nominal phase offset  (Waveguide ONLY). To improve this value, measure and record the phase offset of the Waveguide adapter with dense step size. Enter that value here.

When one connector is coax and the other connector is waveguide, the phase offset has an
ambiguity of 180 degrees. For consistency, the estimate provided here is always between 0 and 180 degrees. You can change this estimate to any value between -180 degrees and +180 degrees.

For SMC calibrations, this dialog box appears twice: once for the input frequencies and once for the output frequencies. The values can be slightly different.
Mixer/Converter Setup

The following dialogs are common to all Converter Apps: FCA, Swept IMDx, IMx Spectrum, NFx, and GCx applications.

**Note:** Swept IMDx, IMx Spectrum, NFx are supported by PNA only. GCx is currently not supported on the M9370A/71A/72A/73A/74A/75A.

- Mixer Frequency tab
- Mixer Setup tab
- Mixer (LO) Power tab
- Fractional Multiplier Examples

**Important Note:** Connecting your Mixer/Converter DUT to the VNA.

**RF** and **IF** terminology is NOT used in this topic because the VNA does not know how your DUT is labeled or how it will be used. Instead, the general terms INPUT and OUTPUT are used to describe the following VNA behavior:

- INPUT - the stimulus frequencies BEFORE conversion by your DUT.
- OUTPUT - the response frequencies, AFTER conversion (either UP or DOWN) by your DUT. Specify UP or DOWN conversion using the + or - symbol for each output.
Settings

**Frequency Format**  Select Start/Stop (Swept) or Fixed. For Linear sweep type, at least one of these must be fixed. For CW or Power, ALL must be Fixed.

**Frequencies** Enter the frequency values for each of the Mixer/Converter ports.

- **Mixer-Product Selector** Determines whether the receivers will tune to the Sum (+) or the Difference (-) of the Input and LO frequencies.

**Calc buttons** Calculates frequency settings based on your other mixer settings. For example, enter the Input frequency range and LO1 frequency range, then press **Calc Output**. The VNA will calculate and display the Output frequencies.

**Input > LO or IF1>LO2** Removes ambiguity when using a Calc button to determine the INPUT frequency.

These check boxes are used ONLY when all 3 of the following conditions are TRUE: (If ALL 3 are NOT true, the VNA does not read these check boxes).

1. Difference (Low) sideband is selected for the corresponding Calculate button AND
2. Output frequency is less than the LO frequency AND

3. One of the Calculate buttons are used to calculate the Input frequency.

**Rules for Configuring a Mixer**

A Red message across the bottom of the dialog indicates that one or more of the following settings are invalid:

- Either ALL ranges (Input, LO, Output) must be Fixed, or ONE Range fixed. TWO ranges can NOT be Fixed or THREE ranges can NOT be Swept.

- For determining a valid mixer configuration with 2 LOs, one Fixed LO and one Swept is equivalent to having a single-stage Swept LO. To configure a 2-stage LO, select Converter Stages: 2 on the Mixer Setup tab.

- INPUT or OUTPUT frequencies cannot be outside the range of the VNA.

- Any combination of INPUT and LO which results in an OUTPUT that sweeps through Zero Hz is NOT allowed.

---

**About Mixer Configuration Files (*.mxr, *.mxrx, or *.csv)**

Save  Saves SOME of the mixer settings to a *.mxr, *.mxrx, or *.csv file.

Load  Recalls a previously-configured mixer *.mxr, *.mxrx, or *.csv file.

**Note:** By default, mixer configurations are saved to a *.mxrX file. Previously, they were saved to a *.mxr file.

ONLY *.mxrx and *.csv files allow saving segmented sweep mixer setups. Currently, only FCA allows segmented sweeps. In all other respects, these new file types are completely backward compatible with *.mxr files.

**What Mixer Settings are Saved?**

- Sweep Type, frequency, and power settings.

- With Segment Sweep Type, all segment settings are saved.

**Converter App Compatibility**

The mixer setup files that are used with FCA, NFx, and GCx for PNA ARE compatible. However, *.mxr(x) files created in IMDx contain information that is NOT included with other
*mxr(x) files.

- When *.mxr(x) files created in other apps files are recalled into IMDx, the VNA attempts a 'best guess' at missing information.
- When IMDx *.mxr(x) files are recalled into other apps, the extra information is ignored.
- When *.mxr(x) files are recalled into an IMx Spectrum channel with any range being swept, the recall is ignored and an error message appears.

**External Sources**

A *.mxr(x) file includes an LO source name. However, it does NOT include the LO Source configuration. Therefore, when using a *.mxr(x) file that was created on a different VNA, the VNA will display an error if it does not find the LO Source configuration using EXACTLY the same LO source name.

**CSV Files**

Mixer configuration files can be saved as a *.csv file. This format was implemented to be used for setting up mixer segments. Start with the GUI to set up mixer settings and to create the first segment then save it as a *.csv file. The GUI can be used to set up multiple segments but is not as convenient as editing an existing Excel *.csv file directly.

The *.csv file has two main categories:

- #BaseSetting
- #MixerSegments

**Note:** The CSV file also supports adding comments. All comments must be added before the #BaseSetting row in the CSV file.

#BaseSetting captures the following fields:
<table>
<thead>
<tr>
<th>Default Columns¹</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumberOfStages²</td>
</tr>
<tr>
<td>SegmentSweepMode</td>
</tr>
<tr>
<td>ReduceIFBandOFF</td>
</tr>
<tr>
<td>CenterSpan</td>
</tr>
<tr>
<td>AvoidSpurs</td>
</tr>
<tr>
<td>PowerCalibrationOn</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Conditional Columns (auxiliary setting): Swept IMD Converter</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMDXSweepType</td>
</tr>
<tr>
<td>IMDXVersion</td>
</tr>
<tr>
<td>RF2</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Conditional Columns: Dual Converter Stage</th>
</tr>
</thead>
<tbody>
<tr>
<td>LO2Numerator</td>
</tr>
<tr>
<td>LO2Denominator</td>
</tr>
<tr>
<td>LO2 (auxiliary setting)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

<tr>
<td>OutputStartPower</td>
</tr>
<tr>
<td>OutputStopPower</td>
</tr>
</tbody>
</table>

---

1. Default columns are always included in the csv.

2. NumberOfStages (previously IsSingleStage) has been moved under ‘#BaseSettings’ and will be used to set converter stage value for each segment.

3. InputPowerMode, OutputPowerMode, LO1PowerMode, and LO2PowerMode (in dual converter stage) have been consolidated into PowerMode in the CSV.

4. Start and Stop powers for Input, Output, LO1, and LO2 (in dual converter stage) are included in the CSV when PowerMode is Swept. When PowerMode is Fixed, these values will be based on the power values from the segments.
For IMDX converter, Start and Stop powers for Input, Output, LO1, and LO2 are included regardless of value in PowerMode column.

#MixerSegments captures the following fields:

<table>
<thead>
<tr>
<th>Default Columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>SegmentNumber</td>
</tr>
<tr>
<td>Dwell</td>

</tbody>
</table>

1. If SegmentSweepMode is true and all the segments have InputRangeMode set to Fixed, then only InputFixedFreq column will be displayed in the CSV.
   If SegmentSweepMode is false and the non-segment configuration’s InputRangeMode is Fixed, the behavior will be the same. This behavior will be true for Output, LO1, IF and LO2 as well.

2. If SegmentSweepMode is true and all the segments have InputRangeMode set to Swept, then only InputStartFreq and InputStopFreq columns will be displayed.
If SegmentSweepMode is false and the non-segment configuration’s InputRangeMode is Swept, the behavior will be the same. This behavior will be true for Output, LO1, IF and LO2 as well.

3 If SegmentSweepMode is true and the segments have a mix InputRangeMode, i.e. segment #1 has Fixed and segment #2 has Swept, then InputFixedFreq, InputStartFreq and InputStopFreq columns will be displayed in the csv. This will be true for Output, LO1, IF and LO2 as well.

The following is an example of an SMC segment sweep csv file:

![Example CSV file](image.png)

For a procedure, refer to How to configure multiple segments using the GUI and Excel *.csv file.

**Apply**  Applies the settings for your mixer/converter test setup to the measurement. The mixer setup dialog box remains OPEN.

**OK**  Applies the settings for your mixer/converter test setup to the measurement. The mixer setup dialog box CLOSES.

**Cancel**  Closes the mixer setup dialog box and does NOT apply the settings.

**Note:** A variation of this dialog is used in the Swept IMDx application. Learn more.

**Converter Stages** Select either 1 or 2-stage converters.

**Hardware Configuration**

Shows the path configuration for Port 3 and Port 4 switches. See Hardware Configurations.

**Add Source** Click to start the External Device Configuration dialog.

**Path Configuration** (PNA Only) Click to start the Path Configuration dialog.

**DUT Ports**

**VMC ONLY** - select the VNA port to connect to the DUT output. The DUT input must always be connected to VNA port 1 because of the need for a reference mixer on port 1.

All other converter applications - select VNA ports to connect to the DUT input and output.

**Fractional Multipliers**

The combination of (numerator / denominator) forms a fractional value that is multiplied by the input and LO frequency ranges. These values are used to calculate the response.
frequency of the VNA receiver for the converter output. Use the fractional multipliers to:

- simulate the action of harmonic mixers
- simulate the action of multipliers and dividers that may exist in your test setup
- tune the VNA receiver frequency to a harmonic of the mixer/converter

The range for the numerator and denominator of a fractional multiplier is from +1 to +10. Negative values are NOT allowed.

See Fractional Multiplier examples.

**LO1 and LO2**

Select *Not controlled* to allow an external source to provide a Fixed LO Frequency at all times. Otherwise, select an internal VNA source or External source to be used as the LO. Learn how to Configure an External Device (Source).

**Fractional Multiplier Examples**

**Example 1**

Use the LO fractional multiplier to replicate the action of the third-harmonic mixer so the VNA can accurately calculate the receiver frequency. The input and LO frequencies are known.
Enter these settings in the **Mixer Setup** dialog box:

- **Input Start Freq**: 30 GHz
- **Input Stop Freq**: 40 GHz
- **LO Fixed Freq**: 16 GHz
- **Mixer-Product Selector**: - (difference)
- **LOs**: 1
- **LO fractional multiplier**: 3/1
- **INPUT fractional multiplier**: 1/1

Click **Calculate Output**

Results:

- **Output Start Freq**: 18 GHz
- **Output Stop Freq**: 8 GHz

---

**Example 2**

Use the fractional multipliers to tune the VNA receiver frequency to the second harmonic of the mixer's 14 GHz fundamental output. The input, LO, and output frequencies are known.

![Diagram](image)

Enter these settings in the **Mixer Setup** dialog box:

- **Input Start Freq**: 4 GHz
- **Input Stop Freq**: 4 GHz
- **LO Fixed Freq**: 10 GHz
- Mixer-Product Selector: + (Sum) of the input and LO signals
- LOs: 1
- INPUT fractional multiplier = 2/1
- LO fractional multiplier = 2/1

Click **Calculate Output**

Results:

- **Output Start Freq**: 28 GHz
- **Output Stop Freq**: 28 GHz

---

**Example 3**

Use the LO fractional multiplier to replicate the action of the divide-by-two mechanism inside the mixer package. Having done this, the VNA can accurately calculate the receiver frequency. The input and LO frequencies are known.

Enter these settings in the **Mixer Setup** dialog box:

- **Input Start Freq**: 45 MHz
- **Input Stop Freq**: 50 MHz
- **LO Fixed Freq**: 670 MHz
- **Mixer-Product Selector**: + (Sum) of the input and LO signals
- **LOs**: 1
- **INPUT fractional multiplier**: 1/1
LO fractional multiplier = 1/2

Click Calculate Output

Results:

- Output Start Freq: 380 MHz
- Output Stop Freq: 385 MHz
With SMC you can optionally measure phase. This feature is available with the S9x083A/B. SMC + phase is NOT offered in the N523xB.

In this topic:

- Overview
- How to make SMC+Phase measurements
- Measuring Mixers below 55MHz
- Comparing SMC+Phase with VMC Phase Measurements
- How to improve the stability of SMC+Phase measurements
- How to Calibrate a 2-stage (LO) SMC+Phase Measurement

Phase Reference Calibration
SMC Measurements and Calibration
SMC+Phase Demo (Internet connection required)

Overview

There are three methods used in the VNA to calibrate SMC+Phase measurements. All three methods rely on newer phase-coherent synthesizers in the VNA to produce phase capability in frequency offset measurements.

With the first two methods, during an SMC calibration, the phase delay through a Calibration Mixer is measured and compared to the known delay. The difference is used to correct subsequent SMC+Phase measurements.

**A Calibration Mixer is required with the first two methods.**

1. Enter the known delay into a dialog.
2. Uses the known delay at various frequencies from an *s2p file from a mixer characterization. You create the *S2P file from a separate Mixer Characterization. This method is NOT supported with Cal All.

3. Uses a Phase Reference to perform a ‘tier 1’ calibration. A Calibration Mixer is NOT required with this process. Learn more about this process.

Notes

- A Reference Mixer is NOT required with any of these methods as it is with VMC.
- SMC+Phase can be measured on Converters with an Embedded LO. Learn how.
- Phase can be measured with Power Sweeps.
- Phase can NOT be measured on Swept LO measurements.
- It is especially important with SMC + Phase measurements to connect the 10 MHz reference signal of an external source to the VNA.
- you can use a Phase Reference Cal Set with Independent power cals for input and output ports (no thru). Learn more.

How to make SMC+Phase measurements

1. On the Mixer Sweep tab, check Enable Phase, then select the Phase Reference Point.

   SMC Mixer Sweep tab - Phase Settings help

   Enable Phase with SMC  Check to perform phase measurements.

   You can also enable phase measurements at the SMC Cal Setup dialog.

   Phase Reference Point

   The SMC Phase measurement technique provides for a coherent phase relationship from one frequency to the next in each sweep. However, the phase measurement of the first data point is random from sweep to sweep. This initial phase offset does not impact measurements such as group delay or deviation from linear phase. However, in order to keep a phase trace from appearing random, all phase data in
the sweep is normalized against a single point. This results in a stable, normalized
phase trace.

For this normalization, select the measurement point that has the best signal-to-
noise ratio. The phase at the selected point will always be zero. This selection
applies for both the measurement and the calibration sweeps.

The Reference Point is fixed at the middle point when segment sweep is selected.

2. Select a Phase Format for the SMC measurement: click Response, then Format, then phase, unwrapped
   phase, or group delay.

3. During SMC Cal, at the Cal Setup dialog, select the Phase Correction method as follows:

   Enable Phase Correction  Check to enable Phase measurements. This can also be
done during the mixer setup.

   Phase Correction

   Choose one of the following methods to specify the known delay through the
characterized mixer. With the first two methods, the phase delay through a
Calibration Mixer is measured and compared to the known delay, either entered, or
stored in an *.S2PX file.

   • Use Known Mixer Delay  Enter the fixed, known, delay through the calibration mixer.

   • Use Characterized Mixer  Select, then browse to the *.S2P file that characterizes the
   calibration mixer. Use an *.S2PX file when making segmented SMC+Phase
   measurements. Learn more. Use either of the following two methods to characterize the
   Cal Mixer over the SMC measurement frequency range:

   1. Use the Mixer Characterization Wizard. The Cal Mixer has the same requirements as
      the VMC Cal Mixer. Learn more.
2. In a calibrated VMC channel, measure the group delay of the calibration mixer, then save to an *.S2P or *.S2PX file. However, a characterized mixer is required to calibrate the VMC channel.

- **Use Phase Reference Calset**: Select, then browse to the Phase Reference Cal Set that covers the frequency range of the current measurement. Learn more about SMC with a Phase Reference.

### Measuring phase on Mixers below 55 MHz

Measuring phase on mixers below 55 MHz is challenging for the following two reasons:

1. The PNA-X couplers have significant losses at these low frequencies. The PNA-X automatically reduces the IFBW at low frequencies in order to compensate for the coupler roll-off. And with SMC+Phase, we recommend setting 100 averages in order to reduce the noise of the SC21 delay measurement. These two settings combine to make the measurement speed VERY slow.

   - **Recommendation**: When measuring a downconverter with an output frequency below 55 MHz, check the “Reversed Port 2 Coupler” checkbox on the SMC Mixer Sweep tab and reverse the Port 2 coupler for the DUT measurement. With this setup, the IFBW is no longer reduced when measuring the output power. This significantly speeds up the measurement without reducing accuracy.

2. The PNA-X has a significant number of **frequency bands** below 55 MHz. SMC+Phase must have multiple measurement points within every frequency band.

   - **Recommendation**: Select the number of data points to yield a point spacing of NO MORE than 200 kHz per point. **Segment Sweep** can be used so that the point spacing above 55 MHz is not as dense.

### Comparing SMC+Phase with VMC Phase Measurements

SMC phase measurements do NOT require a reference mixer, and are therefore easier to make than VMC phase measurements. Also the SMC calibration mixer is only required to have a known delay value, although an S2P characterization file provides more accurate results. The Phase Reference method provides the highest accuracy phase measurements for mixer/converters.

- When measuring converters with an embedded LO, SMC with phase can provide results that are as stable and free from sweep-to-sweep jitter as VMC.

- When measuring converters with an external LO that is shared with the reference mixer (as shown in the **VMC Setup diagram**), VMC provides results that are more stable than SMC+Phase.

### How to improve the stability of SMC+Phase measurements

5799
Stable phase measurements are attained by increasing Sweep Averaging, and sometimes lowering the IFBW, until you attain the desired compromise between sweep time and trace jitter (the amount of random phase change at a single data point). For SMC+Phase, the default IFBW is 10 Hz, and 1 average. During calibration, the Averaging factor is temporarily multiplied by 4 to ensure an accurate phase calibration.

The following procedure shows how to view and improve phase jitter:

1. Create an SMC+Phase channel (Click Response, Measurement Class).
2. Enable Phase with SMC (See above) On the phase trace (to follow) notice that the only point that has NO jitter is the data point that you selected as the Phase Reference point.
3. Change the measurement to IPWR: (Click Response, Measure, IPWR)
4. Change Format to Phase. (Click Response, Format, Phase)
5. Normalize the trace. (Click Math, Memory, Normalize) Learn more about Normalization.
6. Autoscale the trace. (Click Response, Scale, Autoscale).
7. Optionally monitor the jitter with Trace Statistics (Std Dev)
8. Increase Averaging and possibly lower IFBW to improve jitter. (Click Response, Avg BW, then Averaging). Use a MINIMUM of 10 sweep averages (never use Point Averaging).
9. After the adjustments are made, change the measurement back to your measurement of interest.
10. When measuring a new DUT, restart Averaging.

How to Calibrate a 2-stage (LO) SMC+Phase Measurement

Note: The following discussion does NOT pertain when a Phase Reference cal is used to correct the SMC+Phase Measurement.

When calibrating a dual-stage SMC+Phase measurement for group delay using a characterized mixer, the channel setup requires frequency values for two LOs, but the characterized-thru mixer uses only one LO. The frequencies of LO1 and LO2 are different. There are two ways to overcome this challenge:

1. Before the calibration, set the LO that is provided by an external source to uncontrolled. Then manually set the frequency of this external source to the LO frequency that gives the same input and output frequencies, and the same sweep direction, as the dual-stage setup. Perform the calibration under this condition. After the calibration, return the LO to controlled so that its frequency will be properly set during the measurement of the DUT.
2. Configure a 1-stage mixer setup, with the LO set to the frequency that gives the same input and output frequencies and the same sweep direction as the dual-stage setup. Perform the calibration under this condition. Save the calibration data as a user calset. Configure the dual-stage case, and apply the 1-stage calibration.
Phase Reference Calibration

A Phase Reference calibration is performed to simplify the SMC+Phase or MODX (Modulation Distortion Converters) calibration process.

In this topic:

- Features, Requirements, and Limitations
- How it Works
- Hardware Setup
- Phase Reference Calibration Summary
- How to Perform the Phase Reference Calibration

**Other FCA Topics**

**Features**

- Greatly simplified phase measurements on mixers.
- A Reference Mixer or Calibration Mixer is **NOT** required.
- Works well with segmented sweeps, and mixers with 2-stage LOs.

**Requirements**

- One of the following Keysight Comb Generators (Phase Reference):
  - U9391C (26.5 GHz)
  - U9391F (50 GHz)
  - U9391G (67 GHz) - Receiver attenuation must be used.

**Note:** The U9391-60009 sine-to-square wave is recommended when using the instrument’s 10 MHz reference output as the driving source to the comb generator. Connect between the instrument’s 10 MHz output and the input to the comb generator. See the [U9391 Technical Overview](#) for more information.
● Power meter or USB power sensor.

● S-parameter Cal Kit (mechanical or ECal module).

● For measurements below 55 MHz, an additional 'Unknown mixer' is required. Learn more.

● For measurements between 50 GHz and 67 GHz, an additional high-pass filter is required for power calibration. Two back-to-back Keysight V281A waveguide-to-coax adapters is recommended.

**Note:** The 67 GHz comb generator creates a large pulse for generating useful harmonics up to 67 GHz. At low frequencies, receiver attenuation must be used to prevent overloading the VNA receiver due to the large signal. However, above 67 GHz, the extra receiver attenuation causes degradation in the signal-to-noise ratio (SNR) of the high harmonics, which would result in noisy phase calibrations. In order to prevent overloading and get good SNR, the receiver attenuation is removed and a high-pass filter is inserted between the comb generator and the VNA's test port. The calibration wizard provides extra steps to guide the user to insert the filter.

**Limitations**

● Available with opt. S93083A/B (NOT with opt. S93082A/B) Opt S9x083A/B ONLY available on a PNA-X or N522x

● Swept LO measurements are NOT allowed.

● Lowest frequency for Phase Reference Cal is 10 MHz.

**How it Works**

A Phase Reference Cal is performed, saved, and later recalled during a SMC or MODX Calibration. This is sometimes referred to as a 'tier 1" calibration. Due to stability of the VNA, the Phase Reference Cal can be performed infrequently. It is typically performed over the full frequency range of the VNA or Phase Reference so that it can be applied to all SMC or MODX calibrations that will be needed in the future.

The Phase Reference is a comb generator which produces signals at the multiple of its input frequency. By driving it with the VNA 10 MHz reference output, the Phase Reference produces signals at multiples of 10 MHz with a flat phase response.

During the tier 1 calibration, the VNA port 2 (B) receiver measures the phase at each 10 MHz comb frequency in order to generate correction values. These correction values are stored to a Phase Reference Cal Set which can be recalled and applied to correct subsequent SMC+Phase or MODX measurements.
Although only the B receiver is phase calibrated, an S-parameter calibration is performed at specified test ports and used to transfer the characterization to other VNA receivers.

A power calibration is also performed on port 1 as part of the Phase Reference Cal. It does NOT have to be performed again during the SMC or MODX Cal.

**Unknown Mixer Calibration (extends the phase reference calibration below 55 MHz)**

By itself, the phase reference can only be used to calibrate down to 55 MHz. With one additional unknown mixer connection, the phase reference calibration can be extended to the lower limit frequency which is 10 MHz and maximum frequency range of the VNA. The unknown mixer is also used to improve the quality of the phase reference calibration below 300 MHz.

With the unknown mixer process, the phase of the unknown mixer is measured as a down converter with the output frequencies set between 10 MHz and 600 MHz. By using the data acquired using the phase reference, the system is able to make produce calibrated measurements of the mixer above 300 MHz. The phase response of the unknown mixer is assumed to be linear, so the expected phase response of the mixer is extrapolated down to 10 MHz. The variation in the measurements versus the expected phase response is attributed to, and used to correct, the phase response of the VNA receivers from 10 MHz to 300 MHz.

**Unknown Mixer Properties**

- The mixer must be able to output a signal from DC to 1GHz.
- Over these frequencies, the delay response of the mixer should be constant. Therefore, the unknown mixer must be passive, with no filtering or amplification.
- Add a 10 dB attenuator on the mixer input and output to minimize mismatch effects.

**Hardware Setup**

1. Connect the U9391 Phase Reference to a DC power supply by one of the following cables. See the U9391 Technical Overview for more information.

   - The black wire is “ground”.
   - The red wire is +15Vdc. The U9391C and U9391F only require +15 Vdc.

2. Connect a cable from the VNA 10 MHz Reference signal output to the U9391 input. The cable should be as short as possible.
Note: The U9391-60009 sine-to-square wave is recommended when using the instrument’s 10 MHz reference output as the driving source to the comb generator. Connect between the instrument’s 10 MHz output and the input to the comb generator. See the U9391 Technical Overview for more information.

3. Connect the U9391 output directly to the VNA test port 2.

4. Insert the U9391 USB connector into any of the VNA USB ports.

5. Because of its low-frequency roll off, the coupler on Port 2 must be reversed which bypasses the coupled arm. Flip the port 2 front loops as shown in the following image. This increases power to the receiver by approximately 16 dB at low frequencies and removes noise from the measurement.

Configure the Port 2 'B' receiver port front-panel loops to a vertical orientation as shown here.

Block diagram showing port 2 thru coupler main arm to B receiver.

Phase Reference Calibration Summary

The Phase Reference Cal Wizard steps will show the appropriate prompts.

When Unknown Mixer is enabled (Start Frequency is 10 MHz)

- Reverse the Port 2 loops.

- The input and output match of the unknown mixer is measured. Then SC21 is measured using 100 averages.
Phase Reference measurement and S-Parameter calibration below 50 GHz.

- S-parameter cal is NOT performed when Omit Coupler Measurements is checked.
- Reverse the Port 2 loops.
- When using the 67 GHz phase reference, use receiver attenuator or external attenuator.

**When mixer output is above 50 GHz**, Phase Reference measurement and S-Parameter calibration.

- Connect 50 GHz high pass filter to phase reference output.
- Reverse the Port 2 loops.
- Receiver attenuator or external attenuator is NOT used.

Full band power sensor measurement.

- Connect Power Sensor to Port 1.
- Port 2 coupler in normal position.

Full band S-parameter calibration.

- Connect standards to Port 1.
- Port 2 coupler in normal position.
- High-pass filter is NOT used.
- Receiver attenuator or external attenuator is NOT used.
How to start the Phase Reference Calibration

With an Scalar Mixer / Converter + Phase or MODX measurement active...

Using Hardkey/SoftTab/Softkey

1. Press Cal > Main > Other Cals > Phase Reference Wizard....

Using a mouse

1. Click Response
2. Select Cal
3. Select Other Cals
4. Select Phase Reference Wizard...

Phase Reference Cal Settings dialog box help

Use Unknown Mixer

Check to use an Unknown Mixer to calibrate the VNA receivers below 55 MHz. The Start Frequency becomes 10 MHz and can not be changed. Learn how it works.

Ports

- Ports 1 and 2 are always selected.
- Select port 3 and more to perform an S-parameter (SOLT) cal at those ports. The phase correction is transferred to all checked ports.

Start / Stop Frequency

Select the start and stop frequency of the Phase Reference Cal. Subsequent SMC+Phase or MODX calibrations MUST be the same or a subset of these frequencies. Interpolation is
performed when the 10 MHz 'grid' of characterized frequencies is off from measurement frequencies.

- When Unknown Mixer is NOT checked, the lowest start frequency is 55 MHz. The lowest stop frequency is 1 GHz.
- When Unknown Mixer IS checked, the start frequency is 10 MHz and can NOT be changed. The lowest stop frequency is 5 GHz.

### Source Attenuation

Select the attenuation value for the VNA source port.

#### Important Source Attenuation Notes

- This setting should match the port 1 source attenuator setting used for subsequent SMC+Phase or MODX measurements. If the settings are the same, only an S-parameter cal need be performed with the SMC+Phase or MODX calibration wizard to complete the calibration process. If the settings are different, a Cal All calibration must be performed, which requires both an S-parameter cal and another power-sensor cal. As an alternative, if you plan to make SMC+Phase or MODX measurements with different input attenuator settings, you may want to perform a couple of Phase Reference cals using these different attenuator settings.

- The phase reference cal is not as good when using input attenuation. You will get a better calibration if you use 0 dB of source attenuation. Then use the Cal All feature to perform the 2nd tier calibration with the required input attenuation. This is because the Cal All feature includes an attenuator calibration that will properly move the phase reference cal from the 0 dB attenuator plane to the new (required) attenuator plane.

### Phase Reference

When the Phase Reference is detected by the VNA, it should appear in this field. If it does NOT appear here, try a different USB port, then click **Refresh**.

**Phase Reference Connector type and gender.** When the Phase Reference does NOT mate directly with the test port, you can add a well-behaved, broadband (no filters, waveguide, etc.) adapter to the Phase Reference and ignore it. That is because the adapter will stay with the Phase Reference and the calibration plane will still be the VNA test port connectors. The adapter adds constant delay; the deviation in delay is what is being calibrated out. Loss in the adapter is not a concern because the adapter is not used during the S-parameter and the power meter portion of the cal.

### Cal Kit Connector

Select the connector type and gender of your Cal Kit.
Only ONE connector type and gender is specified. This is because the entire Phase Reference cal is performed at the VNA test ports to reduce the effects of cable flex in the characterization.

There may be times when an adapter or connector-savers are used to connect the phase reference and cal standards to the test ports. In these cases, for highest accuracy use that adapter style and gender for ALL connections to ALL test ports. The effects of the adapter will be de-embedded automatically during subsequent SMC+Phase or MODX calibrations.

**Note:** For highest accuracy, perform the phase reference cal at the test ports.

**Cal Kit**  Select the Cal Kit that will be used to perform the S-parameter Cal.

**B Receiver Attenuation**

The 67 GHz (U9391G) phase reference outputs too much power and overloads the VNA Port 2 (B) receiver. Use at least 16 dB and not more that 20 dB of receiver attenuation to make accurate measurements using that phase reference.

This message is shown when a 67 GHz phase reference is connected to USB.

The B receiver attenuator control is shown if your VNA has receiver attenuators. Otherwise, connect external attenuation to the U9391G output when prompted.

**Omit Coupler Measurements**

This choice can be selected when the stop frequency is less than or equal to 50 GHz. Enabling the checkbox simplifies the calibration procedure by reducing the number of calibration steps required, with some tradeoffs. Clearing the checkbox will always result in the most accurate phase-reference calibration.

With the checkbox selected:

- Port 2 can NOT be used as the input to the DUT when setting up subsequent SMC+Phase or MODX measurements.
- The power-sensor calibration is performed at the end of a test cable connected to Port 1, which may degrade the accuracy of conversion loss/gain measurements due to cable movement during the calibration. This problem can be minimized by using a high-quality cable and avoiding cable movement between calibration steps.
Unknown Mixer Settings (Phase Reference Cal Wizard) dialog box help

The following wizard pages appear when Unknown Mixer is checked on the previous page:

**Select LO source**  The LO can be an internal 2nd source or an external source.

**Sources**  Click to start the External Devices dialog where you can select or configure an external RF source.

**LO Frequency**  Select a frequency that results in the unknown mixer output of 10 MHz to 600 MHz using this formula: Input = LO + Output.

**Note:** For best results, use the default LO frequency which avoids the VNA input (source) frequency band crossings.

The Port 2 coupler must be reversed for these measurements. Learn how.

- Connect the unknown mixer input to the between port 1 and port 2. For best results, connect the mixer output as close as possible to port 2.
- Connect the LO of the unknown mixer.
- Click **Measure**.
  - The input and output match of the unknown mixer is measured, then, SC21 using is measured using an averaging count of 100.
  - The data point spacing of the calibration is decreased to 156 kHz. This point spacing is necessary to accurately characterize all the low frequency band breaks of the VNA.
Power Cal Settings (Phase Reference Cal Wizard) dialog box help

A power calibration is performed on port 1. This is done to simplify subsequent SMC or MODX calibrations since the power calibration will not need to be repeated.

For highest accuracy, connect the power sensor directly to the test port with no adapter.

Learn more about these settings.

Phase Reference Calibration Steps dialog box help

- Connect the Phase Reference directly to the port 2 test port.
  
  a. If an adapter is necessary, then that adapter must be left in place for the SOLT cal at port 2.
  
  b. When using a 67 GHz phase reference, attenuation or high-pass filter is required.

- Ensure that the port 2 coupler is reversed. Learn how.

- Press Measure.

- The VNA will make a series of measurements which can take several minutes:
  
  a. First, the match of the phase reference is measured.
b. Then, a sweep is made at multiples of 10 MHz across the entire frequency span. Each measurement is repeated 100 times and averaged to reduce the noise in the measurement.

c. An error is reported if the approximate power level is not detected.

- 5. When finished, press Next>

### Power sensor A

Connect the power sensor to port 1 test port.

**SOLT cals are performed at the test ports.**

- The THRU standard always performs an Unknown Thru.
- Follow the prompts to complete the Phase Reference Cal.

### Phase Ref Cal Finished

Enter a name for the Phase Ref Cal, then click Finished.

During subsequent SMC or MODX calibrations, select the Phase Reference Cal Set at the SMC or MODX Cal setup dialog. Learn more.
If you know the delay value of the Unknown Thru connection, enter it here.

Otherwise, click **OK** to accept the calculated value.
How to make an SMC Fixed Output Measurement

The following is a step-by-step example illustrating how to measure a 1-stage mixer in swept LO mode using FCA Scalar Mixer Calibration.

There are fewer components required for SMC as compared to VMC, and fewer measurement steps. You can now make relative phase measurements with SMC. Also, ONLY SMC (not VMC) can measure the reverse conversion loss of the mixer.

This procedure can also be used for making fixed LO measurements, which is quite similar. Although a second source is still required, when using an external source, the physical triggering cables between the VNA and External Source are not required.

Required Equipment

- PNA-X or PNA ‘C’ models
  - with option S93083A/B (FCA) or option S93082A/B (SMC)
- GPIB External Source. Not necessary when using PNA-X with Internal Second source.
- ECal module with connectors that match the Input and Output connectors of the DUT. You can use adapters to make the ECal module match the DUT connectors, but first perform an ECal user-characterization with the adapters attached. ECal makes the FCA calibration much easier.
- GPIB or USB power meter / sensor
- Cables and adapters

Note: This procedure refers to an External Source to control the LO. If using a PNA-X with an Internal second source, an external source is not necessary. Connect the LO directly to the second source output.

The example mixer

The example device is a down-converter mixer with the following characteristics:

- LO and Input Frequency Range: 2 GHz to 4.2 GHz
- Output Frequency Range: DC to 1.3 GHz

We will measure:
- Fwd Conversion Loss (SC21)
- Input Match (S11)
- Output Match (S22)
- Reverse Conversion Loss (SC12)

**SMC Setup**

Connect the devices as shown in the following diagram:

The DUT can be connected to any VNA ports. Learn more.

This procedure uses DUT input to VNA port 1 and output to VNA port 2.

This procedure refers to an External Source to control the LO. If using a PNA-X with an **Internal second source**, an external source is not necessary. Connect the LO directly to the second source output (port 3 or port 4 on a PNA-X).

**Make Connections on the rear panels:**
1. If using a GPIB power meter, connect the power meter to the external source GPIB connector. If using a USB power meter, connect it to any unused USB port.

2. If using a PNA-X with an Internal second source, the following three steps are not necessary. Connect the LO directly to the second source output.

3. Using a GPIB cable, connect the VNA GPIB controller port to the external source GPIB connector.

4. Using two BNC cables, connect the Source and VNA Trigger connectors as shown in the following image. This is not necessary when making fixed LO measurements.

5. Using a BNC cable, connect the VNA 10 MHz Reference Output to the Ext. Source 10 MHz Reference Input.

![Diagram of Rear Panel Connectors]

Create the Measurement

1. Connect the DUT.

2. Press Setup > External Hardware > Power Meter Setup....

3. Under Interface, select GPIB, then enter the power meter address. Or select USB, then select the USB power meter that is connected to the VNA.

4. Press Preset to make sure you are starting with a known state.

5. Press Meas > S-Param > Meas Class....

6. Press Meas > S-Param > SC21 to replace the S11 trace.

Configure the Mixer settings
1. Press **Freq > Main > SMC Setup...** to start the SMC Setup dialog.

2. On the **Mixer Frequency** tab, enter the Mixer setup values as shown in the image below.

   ![Mixer Frequency Tab](image)

### Notes:

- Rather then enter ALL of the frequency settings, you can enter the Input and the Output frequencies, then click **Calculate LO**.

- If **Input>LO** is NOT checked, the VNA assumes you want the Input < LO frequencies, and higher LO frequencies are calculated as a result.

- The LO power level setting specifies the power out of the external source; not at the DUT) unless an LO power cal is performed.

- When the settings are valid, the background color around the **Apply** button is available.

### Configure the LO Source

1. On the **Mixer Setup** tab:

2. Change LO1 to either an internal VNA source or a pre-configured external source.

3. To configure an external source:

   a. Click **Add Source** in the upper-right corner of the Mixer Setup dialog.

   b. Complete the **External Source Configuration** dialog.

   c. If there is a problem communicating with the source, the VNA will display an error. **See Problems?**

   d. Click **OK** to return to the Mixer Setup dialog.

   e. The new external source is now available as an LO1 selection.

4. Save the mixer settings in a file so you can recall them easily. Click **Save...**, then type a descriptive filename, such as “FixedOutputMixer”.

5. The trace should begin to sweep as the external source steps in frequency. It should look something like this:
Problems?

Not sweeping:

- On the VNA, press Trigger > Main > Continuous to start the VNA sweeping. Watch for error messages on the VNA and source.

Problems communicating with the source:

- Press Setup > External Hardware > External Device... In the External Device Configuration dialog, select your LO source, click on Device Properties..., then click Software CW as the Trigger Mode, then close the dialog. Again, press Trigger > Main > Continuous to start the VNA sweeping. If this works, then something is wrong with Hardware (BNC). Check the trigger cables on the rear panel.

- Can the VNA communicate with the power meter? If not, there is something wrong with the GPIB or USB communication.

- As a last resort, try rebooting the VNA. First, save the entire setup to a .csa file. When the VNA preset measurement appears, recall this .csa file and continue at this step.

If the source is sweeping, and the VNA Input is sweeping, but there is still no output.

- Check power levels at the LO and Input.

- Check the DUT by making a fixed LO measurement - much easier.

Tip: You can optionally calibrate the LO Power level at the DUT using a standard Source Power Calibration. Select the source port in the Source Power Cal dialog.
Perform an SMC calibration

1. Disconnect the DUT.

2. Connect the ECal module to a VNA USB port.

3. Press Cal > Main > Smart Cal... Because the SC21 measurement is active, the Cal Wizard automatically begins an SMC calibration.

4. At the Calibration Setup dialog, click Next.

5. At the Select DUT Connectors and Cal Kits dialog, for DUT Port 1 select the connector type and gender of your DUT INPUT. For DUT Port 2 select the connector type and gender of your DUT OUTPUT. Then select ECal as the Cal Kit to use for each connector. Click Next.

6. At the Scalar Mixer Calibration Step 1 of 2 dialog, connect the power sensor to the Port 1 test cable, then click Measure. The data will be used to correct for input mismatch errors.

7. At the Scalar Mixer Calibration Step 2 of 2 dialog, connect the ECal module Port A to the Port 1 cable, and Port B to the Port 2 cable. Then click Measure. This portion of the calibration gathers the linear (non-frequency-translating) error terms of the test setup at the input and output frequencies.

8. At the Calibration completed dialog, you can choose to save the SMC calibration as a User Cal Set. Otherwise, click Finish to complete the SMC calibration. Correction is turned ON and applied to the SMC trace.

What is happening?

When an external source is sweeping, the measurements are much slower. When correction is ON, you will see that there are times when nothing is happening on the screen. This is because there are background measurements being made but not displayed.

This is exactly the same as when full 2-port correction is applied to an S-parameter. All four parameters are measured, then correction is applied, then all four measurements are updated. This occurs much faster when there is no external source. With correction OFF, the traces are updated as the data is measured. You can see this taking place by creating the following measurements.

Create S12 Upconverter, S11 Input and S22 Output Match

1. Right-click in the window and add new traces to the same channel. Add S11, SC12, and S22 measurement traces.

2. While the source is sweeping, watch the source port indicator on the front of the VNA. First, the port 1 indicator will light for two sweeps, then the port 2 indicator will light for 2 sweeps. During the last sweep, all 4 traces update.

3. Press Cal > Main > Correction Off. Notice that the relevant traces update as the sweep is occurring.
With the SC12 measurement you can see the reciprocity of the mixer.

SMC forward and reverse measurements can reside in the same channel and are calibrated automatically at the same time.
SMC with a Booster Amp

If your mixer measurement requires more source power on the input than the VNA can provide, a booster amplifier can be used to provide the additional power. This topic describes how to configure and make a calibrated SMC measurement using a booster amplifier.

Connect

Connect the booster amplifier between the Source-Out and Coupler-Thru connectors on the front-panel as shown in the following diagram. Your VNA block diagram may not look like this.

Measurement and Calibration Setup

In the following procedure:
- **Test Port power** is the power level out of the source.
- **Corrected power** is the power level you require at the mixer input and output.

This procedure assumes you will applying stimulus power to the mixer **input** to make SC11 and SC21 measurements, and to the **output** of the mixer to make SC22 and SC12 measurements.

1. Determine the gain of the booster amplifier. If the gain has significant slope across the **input and output range** of the mixer, see Booster Amp with a Gain Slope.

2. Determine the corrected power for both the input (port 1) and output (port 2) of the mixer.

3. Calculate the Test Port power for both ports by subtracting the gain of the amplifier from both the input and output corrected power levels.

   For example, the following values assume a 25 dB booster amp on port 1 as in the diagram above.

<table>
<thead>
<tr>
<th>Port</th>
<th>Corrected Power</th>
<th>Amp Gain</th>
<th>Test Port Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port 1 (input)</td>
<td>0 dBm</td>
<td>-25 dB</td>
<td>-25 dBm</td>
</tr>
<tr>
<td>Port 2 (output)</td>
<td>-20 dBm</td>
<td>-25 dB</td>
<td>-45 dBm</td>
</tr>
</tbody>
</table>

4. On the VNA **Power dialog**, clear the **Port Power Coupled** checkbox, which allows different power levels for each port.

5. Enter the calculated **Test Port Power** values for each port.

6. During the SMC Cal Wizard **Select DUT Connectors and Cal Kits** dialog, click **View/Modify Source Cal Settings** to invoke the **Source Calibration Settings** dialog.

7. In **Power Offset**, enter the booster amplifier gain.

**Booster Amp with a Gain Slope**

SMC calibration takes place over the entire input and output range of the mixer. Therefore, the booster amplifier will also be subjected to the entire input and output frequency range of the mixer.

To compensate for a gain slope, you might have to experiment with the source attenuator setting, power-offset value, and initial power value to get a combination that will not cause the VNA source to go unleveled during or after the cal.

For example, assume the booster amp gain is 30 dB at the low end, and 20 dB at the high end. If you
enter 30 dB for the power offset value, the VNA might run out of ALC range when the actual gain drops to 20 dB. The VNA will try to increase its source power to account for the 10 dB gain drop. Therefore, pick a power offset value that is in the middle of the amplifier gain band (25dB).

If possible, select a VNA attenuator setting that puts the ALC approximately in the middle of its range at the desired corrected power with the mid-band gain. This condition means the ALC can set the power higher and lower to account for the gain slope, without unleveling.

If the gain slope is too large, then there may not be a setting that prevents a source unlevel. In this case, a flatter booster amp must be used.
VMC Measurements

VMC Setup and Calibration is very similar to SMC. See FCA Overview to learn about the features that are common to these two applications.

The following information is unique to VMC:

- VMC Hardware Setup
- Create a VMC Measurement
- VMC Parameters Offered
- The VMC Mixer Setup dialog
- VMC Calibrations

See Also

Embedded LO

How to make a VMC Fixed Out measurement

VMC Hardware Setup
DUT Input (RF) must be connected to VNA port 1.
DUT Output (IF) can be connected to any other VNA port.

Notes:

- When using a PNA-X with an Internal Second Source, the external source is NOT necessary.
- See note regarding LO power out both second source ports
- Learn which VNA ports can be used for the LO.
- Measure a DUT with an Embedded LO

Reference Mixer

The Reference mixer provides a phase reference for the measurements. The reference mixer is connected in the reference receiver path of the network analyzer, between the source out and receiver R1 in ports, as shown below.

The reference mixer is considered part of the test system setup like the test cables. It remains in place during the entire calibration and measurement process. The reference mixer is switched in and out of the measurement path by the VNA as needed. See how to manually switch the reference mixer.

The reference mixer does not need to be reciprocal and does not have to match the calibration mixer or the mixer-under-test in performance. The only requirement of the reference mixer is that it cover the same frequency range as the mixer under-test. In general, it is valuable to select a reference mixer that can be used with a variety of different setups. For example, a broadband mixer can be used in place of several narrow-band alternatives.

A low pass filter on the output of the reference mixer can be used to suppress the LO leakage signal that comes out of the reference mixer output. It is not strictly needed, but ensures that the VNA will not have any source unlock or unlevel errors due to the LO leakage.

- Connect the Reference Mixer INPUT to VNA Ref 1 Source out
- Connect the Reference Mixer OUTPUT to VNA Rcvr R1 In

Calibration Mixer/Filter

The Calibration mixer/filter is characterized either before or during a VMC calibration. It is used during the VMC calibration as the THRU standard. The calibration mixer/filter combination must meet the following requirements:

- The mixer must be reciprocal over the frequency range of the mixer under test. This means that it has the same magnitude and phase response in the up-converting and down-converting directions (C21 = C12) as
If the Input and Output frequency ranges are overlapping, the mixer must have Input to Output Isolation greater than 10 dB more than the conversion loss in the overlapping range.

The filter must reject the undesired mixing product, and pass the desired mixing product, at the output of the cal mixer. This requirement can be made easier by characterizing the mixer/filter as a downconverter.

**Note:** With a corrected VC21Swept LO measurement, the phase data is displayed relative to the phase of the calibration mixer that was used during the VMC calibration. In addition, Group delay display format is NOT valid.

See an example of a Fixed Output VMC Measurement

**Important note: Orientation of Reference mixer and Calibration mixer/filter**

The reference mixer is ALWAYS connected in the same orientation as the DUT, since the output frequency of the reference mixer has to match that of the DUT. The same applies to the calibration mixer/filter if it is characterized as part of a full VMC cal.

If you characterize the calibration mixer/filter separately, you can characterize it as either an upconverter or downconverter.

**LO Source**

**Note:** When using a PNA-X with Internal Second Source, the external source is NOT necessary.

- See note regarding LO power out both second source ports
- Learn which VNA ports can be used for the LO.
● Connect **External Sources** to the VNA GPIB Controller port.

● Learn how to **Configure an External LO Source**

**Create a VMC Measurement**

1. Press **Setup > Main > Meas Class...**

2. Select **VMC**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

3. A VC21 measurement is displayed.

4. To select additional parameters to display, press **Trace > Trace 1-8 or Trace 9-16 > Trace N.** to add additional traces.

5. Right-click on the trace, select **Measure TrN...**, then select a parameter from the list then click **OK**.

**VMC Parameters Offered**

**Important Note:** Connecting your DUT to the VNA:

**RF** and **IF** terminology is NOT used in FCA because the VNA does not know how the DUT is labeled or how it will be used. Instead, the general terms **INPUT** and **OUTPUT** are used.

- **INPUT** - The DUT port being stimulated with frequencies before conversion.
- **OUTPUT** - The DUT port outputting converted frequencies.

**INPUT** and **OUTPUT** Frequencies are specified using the **Mixer Setup dialog box**.

The DUT input is always connected to VNA port 1. However, the DUT output can be connected to any other VNA port.

- **VC21, VC31, or VC41 Conversion Loss/Gain (default)** - stimulus at Input, response at Output
- **S11** - stimulus and response at Input
- **S22, S33, or S44** - stimulus and response at Output
- **R1 (or R)** - stimulus at Input, measures absolute power at the R1 receiver (uncorrected)
- **B, C, or D** - stimulus at Input, measures absolute power at the output receiver (uncorrected)
- Reverse conversion loss is NOT offered because of the reference mixer.

### VMC Mixer Setup

#### How to start the VMC Mixer Setup dialog

**Using Hardkey/SoftTab/Softkey**

1. Press *Freq > Main > VMC Setup... > Mixer Setup* tab.

**Using a mouse**

1. Click **Stimulus**
2. Select **Sweep**
3. Select **VMC Setup...**
4. Select **Mixer Setup**

The following VMC Mixer Setup dialog tabs are presented:

- **Sweep Tab** (shared with SMC)
- **Power Tab** (shared with SMC)
- **Mixer Freq Tab** (shared with all converter apps)
- **Mixer Power Tab** (shared with all converter apps)
- **Mixer Setup Tab** (shared with all converter apps)

### VMC Calibration Overview

The Calibration Wizard guides you through this process. The first three steps characterize the calibration mixer that is used as the THRU standard during the calibration process.

1. Perform a **2-port SOLT calibration** over the INPUT frequency range of the DUT, and another **2-port SOLT calibration** over the OUTPUT frequency range. Use either a mechanical calibration kit or an ECal module.
2. Characterize the input and output match of the calibration mixer/filter combination with the external LO connected and the output terminated with an open, short, and load. Learn how to connect the calibration mixer/filter. Once characterized, an S2P file is saved and can be recalled for use in subsequent VMC calibrations using the same stimulus settings. **Note:** Use an *.S2PX file for SEGMENTED VMC measurements. Learn more.

3. Connect the reference mixer between the Source Out and Rcvr R1 front-panel connectors. Connect the output port of the calibration mixer/filter combination to VNA Port 2 (or at the end of the cable attached to the port).

4. Measure the calibration mixer/filter combination as the THRU calibration standard.

5. The VNA calculates the error terms necessary to make corrected phase measurements of your mixer/ converter under test.

**VMC Cal Wizard**

The following dialog boxes are presented during VMC Calibration and VMC Mixer Characterization.

- Calibration Setup
  - Waveguide/In-fixture/On-Wafer Setup
- Calibration Mixer Characterization
- Measurement Direction
- Select DUT Connectors and Cal Kits
  - Modify Frequency Cal
  - Specify how the ECal module is connected
  - Modify Mixer Cal
  - Select the ECal Port to be connected to the Output of the Calibration Mixer
- Vector Mixer Cal Steps
- Measure Calibration Standards
  - Save Mixer Characterization
- Calibration Completed
How to Perform a VMC Calibration

1. Create an FCA measurement, then...

Using **Hardkey/SoftTab/Softkey**

1. Press **Cal > Main > Smart Cal...**

Using a mouse

1. Click **Response**
2. Select **Cal**
3. Select **Smart Cal...**

To perform Mixer Characterization ONLY

1. Press **Cal > Main > Other Cals > Mixer Char Wizard...**

1. Click **Response**
2. Select **Cal**
3. Select **Other Cals**
4. Select **Mixer Char Wizard...**

---

**Calibration Setup** dialog box help

![Calibration Setup dialog box](image)

**Waveguide/In-fixture/On-Wafer Setup**  Check to embed or de-embed circuit networks on the input and output of your mixer under test. Starts the following dialog box.

**Additional Power Cal Steps**
**Enable LO1 / LO2 Power Cal**  Check when LO1 / LO2 is controlled (on the Mixer Setup tab) to perform a Power Cal on the LO source(s).

**Waveguide/In-fixture/On-Wafer Setup** dialog box help

This dialog box appears ONLY if you checked the Waveguide/In-fixture/On-Wafer Setup box in the previous Cal Setup dialog.

Allows you to embed or de-embed circuit networks on the input and output of your mixer under test.

For Network1 (Input) and Network2 (Output) select **Embed, De-embed, or None**.

**Browse**  Click to navigate to the .S2P file that models the network to embed or de-embed.

**Reverse port positions for input/output**  Check to cause the Fixture/Adapter to be configured with Port 2 connected to the VNA and Port 1 to be connected to the DUT. The image in the dialog is updated to reflect that change.

**Enable Extrapolation**  Check (default setting) to apply a simple extrapolation when the S2P file has a narrower frequency range than the channel. The values for the first and last data points are extended in either direction to cover the frequency range of the measurement. A warning message is also displayed when extrapolation is necessary.

**To Embed or De-embed**

- When you have a 2 port network that needs to be connected between the Cal reference plane and the DUT during the measurement, but it is NOT present during the calibration, then that network has to be **De-Embedded** from the port in question during the calibration. In other words, De-Embedding in FCA calibration extends the calibration reference plane to include the two port network.

- When you have a 2 port network that is included as part of the calibration reference plane but has to be disconnected during the measurement, then that 2-port network has to be **Embedded** for the port in question during the calibration. In other words, Embedding in FCA calibration retracts the calibration reference plane to exclude the two port network during the measurement.
Notes

- Interpolation is performed when more frequencies are included in the file than in the channel, and the
data points do not exactly match those of the measurement.

Calibration Mixer Characterization dialog box help

What is Calibration Mixer Characterization? For a brief explanation, see Calibration Mixer.

Select Mixer Characterization Method

Perform Characterization (requires a reference mixer) Performs a Mixer characterization in
addition to the VMC calibration. The mixer characterization file will be saved at the end for use
in subsequent VMC calibrations. Choose this selection if you do NOT already have a mixer
characterization file to load.

Load characterization from file Loads an S2P calibration mixer characterization file. Click
Browse to locate the file.

Note: Load an *.S2PX file for SEGMENTED VMC measurements. Learn more.

- The frequency range of the S2P file MUST be the same, or larger than, the frequency range
  of the FCA measurement. If the S2P file frequency range is larger, or the data points do not
  exactly match those of the measurement, interpolation will be performed.

- The VMC calibration requires that the calibration mixer be connected in the same
  orientation as that in which it was characterized. The direction in which it was characterized
  is not part of the file that is recalled. You have to remember and connect it appropriately.

"Invalid Mixer Characterization File" is displayed if the frequency range of the S2P file is
smaller that those of the measurement.
**Note:** A Mixer Characterization Cal can be performed separately. Learn how.

**Measurement Direction** dialog box help

This dialog box appears ONLY if your settings in the Mixer Setup dialog box indicate that your DUT is being tested as an upconverter (input < output). It allows you to characterize the Calibration Mixer / Filter as a downconverter (input > output) or an upconverter.

The following example shows why you would choose to characterize the calibration mixer as a downconverter. Consider a DUT being used as an upconverter. The input frequency is 70 MHz, the LO is 20 GHz, and the selected (+) output frequency is 20.07 GHz. If we chose (-) in the mixer setup dialog, the output frequency would be 19.93 GHz.

- **Characterize as upconverter** A very sharp cutoff filter is required to reject the undesired output of 19.93 GHz and pass the desired 20.07 GHz.

- **Characterize as downconverter** The input frequency is 20.07 GHz; the LO is 20 GHz. The sum (+) output is 40.07 GHz and the diff (-) output is 70 MHz. These are very easy to separate with a low-pass filter. The original frequencies are always used in the downconversion process, so be sure to choose a filter that will pass 70 MHz and reject 40.07 GHz.

See connection diagrams.
Select DUT Connectors and Cal Kits dialog box help

Allows you to specify the connector type and Cal Kit for each DUT port.

**Port n** For each listed VNA port, specify the DUT connector type and gender, and the Cal Kit to use.

**Mixer Out Port** Output port of the image filter that is connected to the calibration mixer. Specify the Cal Kit / standards to use for the measurement of the calibration mixer / filter combination.

**Note:** When selecting a cal kit for the Mixer Out Port, be sure that the kit has standards with connectors that can mate to the mixer output port. If you choose an ECal, the ECal must have at least one port that can mate to the mixer output port.

**Note:** If your DUT connectors are:

- **Waveguide** Change the system impedance to 1 ohm before performing a calibration. See Setting System Impedance.

- **Not listed** (male and female) Select **Type A** as the connector type. Type A requires a calibration kit file containing the electrical properties of the standards used for calibration (see Calibration kits).

- **Unspecified** (like a packaged device) Select **Type B** as the connector type. Type B requires a calibration kit file containing the electrical properties of the standards used for calibration (see Calibration kits).

**Modify Cal** Check to start the Modify Cal dialog. If performing a Mixer Characterization Cal at the same time as VMC Cal, two Modify Cal dialogs will be presented, one after the other.
**Modify Frequency Cal** dialog box help

For VMC calibrations - NOT for Mixer Characterization.

**Thru Cal Method**  For each Thru connection, choose the Thru method. Learn more about these choices.

**Cal Type/Std**  Click to start the Modify Calibration Selections dialog box.

**The following selections are available ONLY if using an ECal module.**

**Do orientation**  When this box is checked (default) the VNA senses the ECal model and direction in which the ECal module port is connected to the VNA ports. If power to the ECal module is too low, it will appear as if there is no ECal module connected. If you use low power and are having this problem, clear this check box to provide the orientation manually.

Orientation occurs first at the middle of the frequency range that you are calibrating. If a signal is not detected, it tries again at the lowest frequency in the range.

**View/Detect ECal Characterizations**  Appears only if an ECal module is selected for use. Click to invoke the View ECal Modules and Characterizations dialog box. Displays a list of ECal modules that are connected to the VNA.

**Specify how the ECal module is connected** dialog box help

This dialog box appears when the Do orientation checkbox in the previous Modify Frequency dialog box is cleared.

Click the ECal Port that is connected to each VNA port.
Modify Mixer Cal dialog box help

**Mixer Characterization ONLY.** The Thru standard is not measured. Therefore, the Thru Cal Method choices are not available.

**View / Detect ECal Characterizations** Available ONLY if using an ECal module. Invokes the Select ECal Module and Characterization dialog box.

Select the ECal Port to be connected to the Output of the Calibration Mixer dialog box help

Select the ECal Port to be connected to the output of the image filter of the Calibration Mixer / Filter combination. See connection diagram of Calibration Mixer / Filter combination.
**Measure Calibration Standards** dialog box help

Prompts for standards to be measured. Connect the standard, then click **Measure**.

**Measure**  Measures the mechanical standard and continue to the next calibration step.

**[Re]Measure**  Replaces Measure after standard has been measured. Allows you to remeasure a standard.

**Done**  Click to proceed to the **Calibration Complete** dialog. Available only after all measurements for the calibration are complete.

**Back**  Returns to the previous dialog box.

**Next**  Does NOT make a measurement. Proceeds to the next required step.

**Cancel**  Exits the Calibration Wizard.

---

**Vector Mixer Cal Steps** dialog box help

Connect the Open, Short, and Load standards to the image filter output, then click **Measure**.

This portion of the calibration characterizes the calibration mixer.

The connection is different depending on if the calibration mixer is an upconverter being characterized as a down converter.
**Note:**

The following are simplified connection diagrams - the reference mixer and LO signals must also be connected. These images assume that the DUT output is connected to VNA port 2.

As a **Downconverter**. (The VNA automatically switches to make the S22 measurement on the device.)

As an **Upconverter**

**Done** Click to proceed to the **Calibration Complete** dialog. Available only after all measurements for the calibration are complete.
**Save Mixer Characterization** dialog box help

Allows you to save the characterization data of your calibration mixer. When performing another VMC calibration using the same calibration mixer, this S2P file can then be recalled.

**Browse** Navigate to the location where you want to save the characterization data of your calibration mixer. Either use the default file name or enter a custom file name.

**Next** Saves the mixer characterization file and continues with the next step in the full system calibration routine.

**Finish** Replaces Next if you are only characterizing the calibration mixer instead of performing a full system calibration. Saves the mixer characterization file and exits the mixer characterization routine.

---

**Calibration Completed** dialog box help

**Finish** Save to the channel's calibration register.

**Save As User Cal Set** Starts the Save as User Cal Set dialog box AND save to the channel's calibration register.

**Cancel** Calibration is NOT applied or saved.

Learn about Calibration Registers.

Learn about User Cal Sets
Specify delay dialog box help

This dialog appears ONLY when Adapter Removal or Unknown Thru calibrations are performed.

The following values were estimated from the measurement. Most of the time, they are adequate. However, for CW sweep or frequency sweep with large step sizes, the accuracy of the values may be improved.

**Adapter delay**  To improve this value, measure and record the delay of the adapter with a dense step size. Enter that value here. The required precision value is the accuracy that is required to characterize the delay value.

**Nominal phase offset**  (Waveguide ONLY). To improve this value, measure and record the phase offset of the Waveguide adapter with dense step size. Enter that value here.

When one connector is coax and the other connector is waveguide, the phase offset has an ambiguity of 180 degrees. For consistency, the estimate provided here is always between 0 and 180 degrees. You can change this estimate to any value between -180 degrees and +180 degrees.

**For FCA calibrations**, this dialog box appears twice: once for the input frequencies and once for the output frequencies. The values can be slightly different.
How to make a VMC Fixed Output Measurement

The following is a step-by-step example illustrating how to measure a mixer in swept LO mode using FCA Vector Mixer Calibration.

There are fewer components required for SMC as compared to VMC, and fewer measurement steps. You can now make relative phase measurements with SMC. Also, ONLY SMC (not VMC) can measure the reverse conversion loss of the mixer.

This procedure can also be used for making fixed LO measurements, which is quite similar. Although the LO source is still required, the physical triggering cables that connect the VNA and External Source are not required.

**Required Equipment**

- PNA-X or VNA 'C' models
  - with option S93083A/B (FCA)
- GPIB External Source (Keysight ESG or PSG works best). This source is NOT necessary when using PNA-X with Internal Second source.
- Reference Mixer (see requirements)
- Calibration Mixer/Filter (see requirements)
- Power splitter - Not necessary when using PNA-X with Internal Second source.
- ECal module with connectors that match the Input and Output connectors of the DUT. You can use adapters to make the ECal module match the DUT connectors, but first perform an ECal user-characterization with the adapters attached. ECal makes the FCA calibration much easier.
- Cables and adapters
- Optional GPIB Power meter and sensor (for LO power calibration)

**The example mixer**

The example device is a mixer with the following characteristics:

- LO and Input Frequency Range: 2 GHz to 4.2 GHz
- Output Frequency Range: DC to 1.3 GHz
We will measure:

- Fwd Conversion Loss (VC21)
- Input match (S11)
- Output match (S22)
- Rev Conversion Loss is NOT possible because of the reference mixer.

**VMC Setup**

Connect the devices as shown in the following diagram:

**Note:** This setup can also be used for SMC measurements, allowing you to make VMC and SMC measurements simultaneously on separate channels. The Reference Mixer is automatically switched during SMC measurements. The Cal Mixer/Filter is not used.
Notes:

- When using a PNA-X with an Internal Second Source, the external source is NOT necessary.
  - See note regarding LO power out both second source ports
  - Learn which VNA ports can be used for the LO.
- The low-pass filter on the output of the Reference Mixer is recommended, but NOT required. Learn more.
- When using 4-port models, the mixer input must be connected to VNA port 1. The mixer output can be connected to any other VNA port.

Make Connections on the Instrument rear panels:

1. Connect the Source to the VNA GPIB Controller port using a GPIB cable.
2. Using two BNC cables, connect the Source and VNA Trigger connectors as shown in the following image. This is not necessary when making fixed LO measurements, or using a PNA-X with Internal Second Source.
3. Using a BNC cable, connect the VNA 10 MHz Reference Output to the Ext. Source 10 MHz Reference Input.

Create the Measurement

1. Connect the DUT.
2. Press Preset to make sure you are starting with a known state.
3. Press **Meas > Main > Meas Class**.

4. Select **Vector Mixer/Converter** then **OK**. At the **Confirm**... dialog, click **OK**. An S11 trace is created.

5. Press **Meas > Main > VC21** to replace the S11 trace.

Configure the Mixer settings

1. Press **Freq > Main > VMC Setup**... to start the VMC Setup dialog.

2. On the **Sweep** tab, no changes from the default settings are required. The Avoid Spurs feature is useful for eliminating spurs in test setups with excessive LO leakage.

3. On the **Power** tab, change the DUT Input Port Power Level to -17 dBm.

4. On the **Mixer Frequency** tab, enter the frequency values as shown in the following image:

![Mixer Frequency Tab](image)

   a. You can enter the Input and the Output frequencies, then click **Calc LO**.

   b. If **Input > LO** is NOT checked, the VNA assumes you want the Input < LO frequencies, and higher LO frequencies are calculated as a result.

External Source Configuration

When using a PNA-X with Internal Second Source, the external source is NOT necessary.

* See note regarding LO power out both source ports

* Learn which VNA ports can be used for the LO.

1. On the **Mixer Setup** tab, click **Add Source** to start the External Source Configuration dialog. Learn how to configure an external source.

2. On the External Source Configuration dialog, click **Device Properties**.

   a. Click **Hardware List (BNC)**, which is the fastest measurement method. This method requires the BNC Trigger cables that connect the VNA and source. If not available, **Software CW** can be used, but measurements are much slower.
b. If necessary, select the Interface (usually GPIB), then Refresh, then select the Available IO Configuration.

c. Click OK to close the Device Properties dialog, then OK to close the External Source Configuration dialog.

3. Next to LO1, select the configured external source name.

**Complete Mixer Setup**

1. On the Mixer Power tab, change LO1 Power to 0.00 dBm. This setting specifies the power out of the external source (not at the DUT) unless an LO power cal is performed.

2. When the settings are valid, the Save, Apply and OK buttons are available to click. To save the mixer settings in a file so you can recall them easily, click Save..., then type a descriptive filename. Then click OK.

3. Click OK to close the VMC Setup dialog.

4. To change the X-axis values from the default Output selection (800 MHz), press Sweep > Main > X-Axis Type > Input.

5. The trace is updated as the external source steps in frequency. It should look something like the following image. Because of the reference mixer, the uncorrected VMC measurement can look like it has gain.
Problems?

Not sweeping:

- On the VNA, press **Trigger > Main > Continuous** to start the VNA sweeping. Watch for error messages on the VNA and source.

Problems communicating with the source:

- Press **Setup > External Hardware > External Device...** On the External Device Configuration dialog, select the external source, then click Device Properties. Next to Trigger Mode: select **Software CW trigger**, then close the dialog. Again, press **Trigger > Main > Continuous** to start the VNA sweeping. If this works, then something is wrong with **Hardware (BNC)**. Check the trigger cables on the rear panel.

- As a last resort, try rebooting the VNA. First, save the entire setup to a \*.csa file. When the VNA preset measurement appears, recall the \*.csa file to resume at this step.

If the source is sweeping, and the VNA Input is sweeping, but there is still no output.

- Check power levels at the LO and Input.
- Check the DUT by making a fixed LO measurement which is much easier.

Perform a VMC Calibration

1. Disconnect the DUT.

2. Connect the ECal module to a VNA USB port.

3. Press **Cal > Main > Smart Cal...**. Because the VC21 measurement is active, the Cal Wizard automatically begins a VMC Calibration.

4. At the Calibration Setup dialog, click **Next**. Or check Enable LO1 Power Cal to perform a Source Power Cal to specify the LO Power at the DUT. This requires a power meter or USB power sensor be connected.

5. At the Calibration Mixer Characterization dialog, click **Next**. We will perform characterization of the Calibration mixer as part of the VMC cal. Later we will save the Calibration mixer characterization so that, in future VMC calibrations that use this same frequency range, we can recall the Calibration mixer characterization by clicking **Load Characterization from file**.

6. At the Select DUT Connectors and Cal Kits dialog, for Port 1 select the connector type and gender of your DUT INPUT. For Port 2 select the connector type and gender of your DUT OUTPUT. Then select ECal as the Cal Kit to use for each connector. Click **Next**.
7. At the **Select the ECal Port to be Connected** dialog, ensure that **Port A** is selected for **Port 1**, then click **Next**.

8. At the **Vector Mixer Calibration Step 1 of 3** dialog, connect the ECal module Port A to the Port 1 cable, and Port B to the Port 2 cable. Then click **Measure**. This portion of the calibration gathers the linear (non-frequency-translating) error terms of the test setup at the input and output frequencies.

9. At the **Vector Mixer Calibration Step 2 of 3** dialog, connect the following, then click **Measure**. This portion of the calibration will connect reflection standards to characterize the S-parameters of the calibration mixer/filter.

   - Port 1 cable to the Input of the calibration mixer.
   - LO cable to the LO port of the calibration mixer.
   - ECal module to the Output of the calibration mixer/filter.

10. At the **Vector Mixer Calibration Step 3 of 3** dialog, disconnect the ECal module and connect the Port 2 cable to the output of the calibration mixer/filter, then click **Measure**. This step completes the calibration using the characterized mixer/filter as a Thru standard.

11. At the **Save Mixer Characterization** dialog, click **Browse**, then type a unique filename and click **OK**. Then click **Next**. This saves the Calibration Mixer characterization to an S2P file. This file can be recalled for subsequent VMC calibrations.

12. At the **Calibration completed** dialog, you can choose to save the VMC calibration as a User Cal Set. Otherwise, click **Finish** to complete the VMC calibration. Correction is turned ON and applied to the VMC trace that we set up earlier.

### What is happening?

When an external source is sweeping, the measurements are much slower. When correction is ON, you will see that there are times when nothing is happening on the screen. This is because there are background measurements being made but not displayed.

This is exactly the same as when full 2-port correction is applied to an S-parameter. All four parameters are measured, then correction is applied, then all four measurements are updated. This occurs much faster when there is no external source. With a VMC measurement, there is no VC12 (reverse transmission measurement), so there are only three background measurements. With correction OFF, the traces are updated as the data is measured. You can see this taking place by creating the following measurements.

### Create S11 Input and S22 Output Match

1. Right-click in the window and add new traces to the same channel. Add **S11** and **S22** measurement traces.
2. While the source is sweeping, watch the source port indicator on the front of the VNA. First, the port 1 indicator will light for two sweeps, then the port 2 indicator will light for 1 sweep while all 3 traces update.

3. Press **Cal > Main > Correction Off**. Notice that the relevant traces will update as the sweep is occurring.

The following image shows the corrected Conversion Loss (VC21), Input Match (S11), Output Match (S22) and the uncorrected Conversion Loss (VC21), which is a memory trace.
Embedded LO Measurements

The Embedded LO feature allows you to make VMC, SMC, IMDx, GCX, MODX and NFX measurements of mixers that have a FIXED LO inside the DUT. Learn how to make IMX Spectrum measurements on converters with an Embedded LO.

Note: This feature is available as Opt S9x084A/B, and must be enabled.

In this topic:

- Overview - How the VNA measures the embedded LO
- To measure a DUT with an Embedded LO (Procedure)
- How to Launch the Embedded LO Mode dialog box
- Embedded LO dialog box help
- Embedded LO Diagnostic dialog box help

Overview - How the VNA measures the embedded LO

Measurements of these devices are challenging for a couple of reasons:

1. The VMC measurement process requires the use of a reference mixer that has the same LO frequency as the DUT. A separate internal or external source must be used for the reference mixer LO. A VNA with an internal second source is much faster. This source (Internal or External) MUST be controlled by the VNA! Learn how.

2. All Embedded LO measurements require the VNA receivers to be tuned to the correct frequency to measure the mixer output, which is highly dependent on the exact LO frequency.

The nominal frequency of the embedded LO is input into the Mixer Setup dialog. This is used as a starting point for the measurement.

Before each DUT measurement sweep, background sweeps are made to determine the frequency of the embedded LO to a configurable degree of accuracy.

Background sweeps...

- **Broadband** Sweep - rough measurement of the embedded LO frequency, made around a selectable data point over a selectable frequency span. The input signal to the DUT is tuned to a selectable CW frequency. The B receiver is swept across a selectable span around the anticipated output frequency. The difference
between the frequency of the found signal and the desired output frequency is then applied as an adjustment.

- **Precise Sweep** The B receiver is measured at the selectable data point. Measurements of phase versus time are made, from which the exact offset frequency is computed, until either the tolerance value or maximum iterations are met.

- For VMC measurements, the reference mixer frequency is updated as the embedded LO frequency is determined.

**To measure a DUT with an Embedded LO:**

1. Create a VMC, SMC, IMDx, IMx Spectrum, GCX, or NFX measurement.
2. In the mixer setup dialog, enter the nominal frequency of the embedded LO as the LO frequency.
3. Perform a calibration as usual.
4. Launch and complete the Embedded LO Mode dialog box (below)

**For VMC with Embedded LO:**

(The other mixer applications do NOT require a reference mixer.)

The LO source for the Reference Mixer can be either:

- An **Internal** source when using a PNA-X that has two sources.
- An **External** source:
  - Must be configured as an External Device. Learn how.
  - Must be locked to the VNA using the 10 MHz reference.

This source (Internal or External) **MUST be controlled by the VNA**. To control the source, set the LO1 source in the Mixer Setup tab to whichever source (external, port 3, or port 4) that is driving the reference mixer.

**During Calibration** - The LO source is shared between the Reference Mixer and the Calibration Mixer/Filter. This requires a splitter when using an external source, as shown in the following image.
**During the Measurement** - Only the Reference Mixer uses the LO source. Terminate the LO source port that is no longer used by the Calibration Mixer/Filter to ensure that the match seen by the Reference Mixer LO port does not change after the calibration, as shown in the following image. This precaution is not necessary when using the internal second source (ports 3 and 4) of the PNA-X.
For SMC, IMDx, IMxSpectrum, and NFX measurements:

No unique setup is required for embedded LO measurements.

**How to Launch the Embedded LO Mode dialog box**

**Using Hardkey/SoftTab/Softkey**

1. Press **Sweep > Source Control > Embedded LO...**

**Using a mouse**

1. Click **Stimulus**
2. Select **Sweep**
3. Select **Source Control**
4. Select **Embedded LO...**
The Tuning Settings balance LO measurement speed versus accuracy. You can see that accuracy is becoming compromised when noise starts to appear on the measurement trace.

Scroll up to learn more about the Embedded LO measurement process.

Enable Embedded LO  Check to enable measurement of the Embedded LO.

Tuning Method  These settings determine the amount of time spent versus the degree of accuracy to which the LO Frequency is measured. You can see that accuracy is becoming compromised when noise starts to appear on the measurement trace.

Broadband and Precise  Does the entire tuning process for each background sweep. See the Overview for more information.

Precise only  Does NOT perform broadband tuning on each sweep. Use this setting when the embedded LO is stable. The signal (after broadband) must be within ½ the tuning IFBW. If the signal will always be within ½ the IFBW, broadband tuning is not needed. Most satellite components are within 3 kHz absolute so might not need broadband tuning.

Disable tuning  Only the previously measured LO Frequency Delta is applied to the reference mixer LO and VNA receivers.

Tuning Point  Select, or specify, the data point in the mixer sweep that will be used to find the
embedded LO frequency. If a marker is enabled, that data point can be used. For broadband and Precise sweeps, choose a point in the mixer sweep where noise is least likely to be found, such as the point of highest gain. This is generally the center of a sweep or the center of a filter if used.

**Tune every** Set the interval at which tuning is performed before a measurement sweep. 'Tune every 3 sweeps' means that every third measurement sweep is preceded by tuning sweeps. If the embedded LO drifts, or if regularly changing DUTs, use 'Tune every 1 sweep'.

**Broadband Search** - Set the frequency span over which to measure the embedded LO frequency.

**IFBW** IF Bandwidth used for Broadband and Precise tuning sweeps. This sets the resolution in the Broadband sweeps and sets the max error (1/2 IFBW) for precise tuning. The larger the IFBW, the faster the sweep, but the signal may not be found.

**Max Iterations** The maximum number of Precise sweeps to make. When this number is reached, the final measurement is used.

**Tolerance** When two consecutive Precise measurements are made within this value, the final measurement is used. If this is not achieved within the Max Iterations value, then the last measurement is used. This is the best of the 'Tunings settings' to change to improve accuracy.

**LO Frequency Delta** The absolute difference between the measured embedded LO frequency and the LO setting that is entered in the Mixer Setup dialog. This value is updated each time the embedded LO frequency is measured. Entering a value is a way to change the LO frequency on the mixer setup without invalidating the calibration.

**Find Now** The VNA finds and measures the actual LO frequency using the current dialog settings. This data is displayed in the Status box.

**Status window** Displays textual and graphical representation of the Embedded LO measurement sweeps.

**Default** Resets the LO Frequency Delta and Tuning parameters to their default settings.

**Graph...** Launches the graphical (spectrum analyzer type) display sweeps of the latest embedded LO measurement.
This dialog appears when **Graph** is clicked on the **Embedded LO** dialog.

Presents a graphical (spectrum analyzer type) display of the latest embedded LO measurement.

Click **Previous** and **Next** to view available Broadband and Precise sweeps. The LO Frequency is displayed in the Marker annotation.
Frequency Offset Mode

Frequency Offset Mode (FOM) provides the capability to have the VNA Sources tune to frequencies that are different (offset) from the VNA Receivers.

VNA Option 080 or S9x080A provides you with the hardware and basic software capability to make Frequency Offset Measurements. This topic discusses the VNA settings that are relevant to making these types of measurements. See Frequency Converting Device Measurements for more information on making specific device measurements.

- Frequency Offset Dialog Box
- Setup Examples
- RF Path Config (Reference Switch) Dialog Box

Other Frequency Offset topics

How to make Frequency Offset settings

Using Hardkey/SoftTab/Softkey

1. Press **Sweep > Source Control > Frequency Offset...**
The following are major changes to FOM:

- Stimulus and Response are now called Sources and Receivers.
- Sources and Receivers settings can be made in two ways:
  1. **By Coupling** to the Primary (Channel) settings. This is the only method used in previous releases.
  2. **By Uncoupling** and setting Sources and Receivers values independently. This is the new, simplified method.
- External sources appear here and can be controlled from this dialog. [Learn more]

**Note:** Source2 supplies power for ports 3 and 4. **Turn Source2 power ON** using the Power and Attenuators dialog. This (Frequency Offset) is the only dialog for controlling the frequency of Source 2. [Learn more about Source2]

**Note:** Source3 is an RF signal to the rear-panel connector. **Turn Source3 power ON** using the Power and Attenuators dialog. This (Frequency Offset) is the only dialog for controlling the frequency of Source 3. [Learn more about Source3]

**Frequency Offset (ON/OFF)** Enables Frequency Offset Mode on ALL measurements that are present in the active channel.

When FOM is NOT enabled, all frequencies are the same as the active channel.

**Tip:** First make other settings on this dialog box, then click **Frequency Offset ON**.

**Primary** The current Active Channel settings. When a Source or Receiver is coupled to the Primary settings, its Sweep Type is the same as that of the Primary. The frequency settings of the coupled range are mathematically derived from the Primary settings using the Multiplier, Divisor, and Offset values. With this approach, only the Primary settings need to be changed in order to affect change in the coupled Sources and Receivers. Changes to the Primary channel settings occur when Frequency Offset is checked ON. [See example using Primary and Coupled setting]

**Tip:** Primary settings are ONLY used when Sources and Receivers are Coupled. It is often easier to Uncouple, then set Sources and Receivers independently.

Source and Source2 if available. [Learn more about Internal Second Source]

**Receivers** All receivers that are used in the channel, including Reference receivers, are tuned to
the specified frequency settings.

**Mode**

**Coupled**  Source and Receiver settings are mathematically derived from the Primary settings using Multiplier, Divisor, and Offset values.  [Learn more.]

**Uncoupled**  Source and Receiver settings are entered independently, without reference to Primary settings. When Uncoupled, Source and Receiver Ranges can use separate sweep types.

**Sweep Type**  Click to change the type of sweep for each range. Only available for Primary and Uncoupled Sources and Receivers.

**Unsupported Sweep Type combinations**

- Power Sweep and Segment Sweep can NOT be used together.
- Uncoupled Log Sweep yields invalid data whenever the sources are offset from the receivers.
- Coupled Log Sweep is allowed only for the following two conditions:
  1. The offset = 0, the multiplier = 1, and the divisor = 1.
  2. The multiplier = 0

**Settings**  To change settings, click **IN** the appropriate Settings cell, then click **Edit**.

- If coupled, invokes the **Coupled dialog**.
- If uncoupled or Primary invokes the **Uncoupled settings dialog**.

**X-Axis Annotation**  Select the settings to be displayed on the X-Axis:

**X-Axis Point Spacing**  Only available when a Segment Sweep Type is selected as the X-Axis display.  [Learn more.]
**Note:** When Frequency Offset is enabled, ALL receivers on the channel, including the reference receivers, tune to the new offset frequencies. Therefore the source and reference receiver will be at different frequencies. Therefore, FOM measurements that include a reference receiver, which includes all S-parameters, display invalid data.

To measure and display measurements at both the source and receiver frequencies, you must use two channels. Use **Equation Editor** to calculate the conversion loss. See a calibrated FOM conversion loss example.

Learn how to calibrate frequency offset measurements.

---

**Coupled settings** dialog box help

**Coupled Formulas:**

\[
\text{Range Start} = \left[ \text{Primary Start} \times \left( \frac{\text{Multiplier}}{\text{Divisor}} \right) \right] + \text{Offset}
\]

\[
\text{Range Stop} = \left[ \text{Primary Stop} \times \left( \frac{\text{Multiplier}}{\text{Divisor}} \right) \right] + \text{Offset}
\]

Where:

**Offset**  Specifies an absolute offset frequency in Hz. For mixer measurements, this would be the LO frequency. Range is +/- 100 GHz. Offsets can be positive or negative.

**Multiplier**  Specifies (along with the divisor) the value to multiply by the stimulus. Range is +/- 100.

- Negative multipliers cause the stimulus to sweep in decreasing direction. For downconverter mixer measurements, this would be for setups requiring the Input frequency to be less than LO frequency. See an example.
- 0 (zero) as the multiplier nulls the Primary setting. Then the Offset value adds to zero.

**Divisor** Specifies (along with the multiplier) the value to multiply the stimulus. Range is 1 to 100.

---

**Primary and Uncoupled settings** dialog box help

![Primary and Uncoupled settings dialog](image)

This dialog will vary depending on the sweep type:

**Linear and Log frequency**

Uncoupled Log sweep yields **invalid data** whenever the sources are offset from the receivers.

- **Select Start/Stop or Center/Span**
- **Frequency** Enter values
- **Points** (Primary only) Enter number of data points for the sweep.

**Power**

- **CW Freq** Enter frequency in Hz.
- **Points** (Primary only) Enter number of data points for the power sweep.

**CW Time**

- **CW Freq** Enter frequency in Hz.
- **Sweep Time** Enter time to complete one sweep. Enter 0 for the fastest sweep.

**Segment Sweep** Edits are made exactly like the **standard segment table**.
**For Advanced Users:** Uncoupled Segment Sweep offers great flexibility in configuring measurements. In segment sweep mode:

- The **OK** button is NOT available until the total number of data points for all segments matches the number of Primary data points.

- **Independent IF Bandwidth** and **Independent Sweep Time** are available ONLY on the Primary (channel) and the Uncoupled **Receivers** - NOT Sources.

- **Independent Power** is available ONLY on the Primary (channel) and the Uncoupled **Sources** - NOT Receivers.

**Setup Examples**

Although the Frequency Offset settings can be used with many types of devices, these examples include mixer terminology.

See a Mixer Compression and Phase (AM-PM) Measurement using FOM.

See a calibrated FOM conversion loss example.

1. **Fixed LO - Upconverter**

   - **Swept Stimulus (Mixer Input):** 1000 MHz - 1200 MHz
   - **Fixed LO:** 1500
   - **Swept Response (Mixer Output):** 2500 MHz to 2700 MHz

   Make the following settings on the FOM dialog

   **Source:** Uncoupled

   - Sweep Type: Linear

   - Click Settings, then Edit. In the Source dialog:
     - Start Frequency = 1000 MHz
     - Stop Frequency = 1200 MHz

   **Receiver:** Uncoupled

   - Sweep Type: Linear
Click Settings, then Edit. In the Receiver dialog:

Start Frequency = 2500 MHz

Stop Frequency = 2700 MHz

**LO Settings**

Set external source to CW - 1500 MHz.

**Source2**: Uncoupled (Only with Second VNA Internal Source)

Sweep Type: CW Time

Click Settings, then Edit. In the Source2 dialog:

CW Frequency = 1500 MHz

2. **Fixed LO - Downconverter (Input < LO)**

- **Swept INCREASING Stimulus (Mixer Input)**: 1000 MHz to 1100 MHz
- **Fixed LO**: 2500 MHz
- **Swept DECREASING Response (Mixer Output)**: 1500 MHz to 1400 MHz

Make the following settings on the FOM dialog

**Primary**: Not used

**Source** (Input): Uncoupled

Sweep Type: Linear

Click Settings, then Edit. In the Source dialog:

Start Frequency = 1000 MHz

Stop Frequency = 1100 MHz

**Receiver** (Output): Coupled

Sweep Type: Linear

Click Settings, then Edit. In the Receiver dialog:

Offset: 2500 MHz
Multiplier: -1 (Minus one)

LO Settings

- If using external source, set to CW: 2500 MHz.
- If using Source2: Set to Uncoupled, then:
  
  Sweep Type: CW Time
  
  Click Settings, then Edit. In the Source2 dialog:
  
  CW Frequency = 2500 MHz

See a calibrated FOM conversion loss example.

3. **Swept LO - Fixed Output - Upconverter**

Swept External LO measurements in Frequency Offset Mode can be very difficult. The external LO source must be synchronized with the swept output or input (as in this case). See Synchronizing and External Source Control to see how this is done. The Frequency Converter Application Opt S9x083A/B performs makes these measurements easily.

- **Swept Stimulus (Mixer Input):** 1000 MHz to 1100 MHz
- **Swept LO:** 1500 MHz to 1400 MHz
- **Fixed Response (Mixer Output):** 2500 MHz

Make the following settings on the FOM dialog

**Source:** Uncoupled

Sweep Type: Linear

Click Settings, then Edit. In the Source dialog:

Start Frequency = 1000 MHz

Stop Frequency = 1100 MHz

**Receiver:** Uncoupled

Sweep Type: CW Time

Click Settings, then Edit. In the Receiver dialog:
CW Frequency = 2500 MHz

LO Settings

- If using external source, set to sweep from 1500 - 1400 MHz.
- If using **Source2 (Second Internal Source)**: set to Uncoupled, then:

  Sweep Type: Linear
  
  Click Settings, then Edit. In the Source2 dialog:

  Start Frequency = 1500 MHz
  
  Stop Frequency = 1400 MHz

4. **Power Sweep for Mixers**

   To measure the gain compression of a mixer, the input power to the mixer is swept. The input and output frequencies are fixed but offset from one another.

   This is a good use of Coupled settings because the same compression test can be performed at several different frequencies. With coupled Source and Receiver ranges, the Primary (channel) frequency can be easily changed from the front panel. The coupled source and receiver frequencies will update accordingly.

   - **Swept Input Power**: -10 dBm to 0 dBm
   - **Fixed Input Frequency**: 1500 MHz
   - **Fixed LO**: 500 MHz
   - **Fixed Output**: 2000 MHz

   Make the following settings on the FOM dialog

   **Primary**:

   Sweep Type: Power Sweep

   Click Settings, then Edit. In the Primary dialog:

   CW Frequency = 1500 MHz

   **Source**: Coupled
Default settings make CW Frequency: 1500 MHz (same as Primary)

**Receiver:** Coupled

Default settings make Sweep Type: CW Time

Click Settings, then Edit. In the Receiver dialog:

**Offset = 500 MHz**

**LO Settings**

- If using external source, set to CW: 500 MHz.
- If using **Source2 (Internal Second Source)**, set to Coupled, then:

  Sweep Type: Power Sweep

  Click Settings, then Edit. In the Source2 dialog:

  **CW Frequency = 500 MHz**

---

**Test Set Reference Switch**

PNA-X and N522x models have a switch in the test set that allows you to bypass the port 1 reference receiver through the front panel Reference 1 connectors. This switch lets you easily switch between standard S-Parameter measurements and measurements using a reference mixer. You could use this feature to make standard S11 measurements and converter transmission measurements relative to a reference ("golden") mixer.

**Note:** The Frequency Converter Application Option S93083A/B simplifies the task of making extremely accurate phase measurements on MOST frequency converting devices.

---

**Programming Commands**
**RF Path Config dialog box help**

![RF Path Config](image)

**Note:** This feature is available on PNA-X and N522x models.

**R1 Input Path**

- **Internal**  Connects the port 1 source directly to the R1 receiver.
- **External**  Allows direct access to the R1 receiver through the Reference 1 front-panel connectors.

See specifications which include a block diagram of reference switch.
Frequency Converting Device Measurements

Many frequency offset measurements can be made using the VNA with S93080A. The following is a list of some of those measurements and how they are made.

- Conversion Loss
- Conversion Compression
- Return Loss and VSWR
- Isolation
- Harmonic Distortion

See Also: Frequency Offset Measurement Accuracy
Frequency Offset Measurement Accuracy

This topic discusses methods that can be used to make accurate frequency offset measurements.

- Calibrations
- Mismatch Errors
- Accurate and Stable LO

See other Mixer Measurement topics

Calibrations

With Frequency Offset measurements, the stimulus and response frequencies are different. Standard calibration error terms are calculated using reference measurements. Therefore, traditional calibration methods such as full 2-port SOLT cannot be used with frequency offset.

Source and Receiver Power calibrations can be used to calibrate your Frequency Offset measurements.

Frequency Converter Application offers fully calibrated scalar and vector frequency offset measurements.

Source Power calibration:

- Sets accurate power level at stimulus frequencies regardless of the receiver that will be used in the measurement.
- Can be copied to other channels with copy channels feature.
- Can be interpolated.

Receiver Power Cal:

- Requires a source cal to have already been performed and applied.
- Cannot be copied to other channels.

Therefore:

- Start by performing a source power cal over the combined stimulus and response frequencies.
• Copy the channel to other needed channels and the source power cal is copied.

• Change the frequency range of the copied channel to response frequencies.

• Perform a receiver cal at the response frequencies on individual channels.

• Change the frequency range to stimulus frequency and switch frequency offset ON.

• On Status Bar, ensure that source and receiver cals are ON (source cal will be interpolated).

See Frequency Offset Conversion Loss Measurements to see a step-by-step example.

Mismatch Errors

Mismatch errors result when there is a connection between two ports that have different impedances. With S-parameter measurements, these mismatches are measured and mathematically removed during a full 2-port calibration. This is much more difficult with frequency offset measurements. A much easier solution is to use high-quality attenuators on the input and output of the mixer.

By adding a high-quality attenuator to a port, the effective port match can be improved by up to twice the value of the attenuation. For example, a 10-dB attenuator, with a port match of 32 dB, can transform an original port match of 10 dB into an effective match of 25 dB. However, as the match of the attenuator approaches the match of the original source, the improvement diminishes.

Note: The Frequency Converter Application (option S93083A/B) uses calibration techniques that correct for mismatch errors.

The larger the attenuation, the more nearly the resulting match approaches that of the attenuator, as shown in the following graphic. However, excessive attenuation is not desired because that will decrease the dynamic range of the measurement system.
Accurate and Stable LO

When using frequency offset mode, if the LO signal is not accurate and stable, the output signal will not be at the expected response frequency. As a result, the output signal can fall on the skirts of the VNA receiver IF filter, or fall completely outside of the receiver filter passband.

Also, the LO power level is critical in mixer measurements. Be sure to monitor these power levels closely.
Conversion Loss (or Gain)

- What is Conversion Loss?
- Why Measure Conversion Loss?
- How to Measure Conversion Loss

See other Frequency Converting Device Measurements

What is Conversion Loss?

Conversion loss is defined as the ratio of the power at the output frequency to the power at the input frequency with a given LO (local oscillator) power. This is illustrated in the graphic below. A specified LO power is necessary because conversion loss varies with the level of the LO, as the impedance of the mixer diode changes.

![Conversion Loss Diagram](image)

Why Measure Conversion Loss?

Conversion loss (or gain in the case of many converters and tuners) is a measure of how efficiently a mixer converts energy from the input frequency to the output frequency. If the conversion loss response of a mixer or converter is not flat over the frequency span of intended operation, valuable information may be lost from the resulting output signal.
How to Measure Conversion Loss

Conversion loss is a transmission measurement. It is measured by applying an input signal (stimulus) and an LO signal at specific known power levels, and measuring the resulting output signal level. Because the output frequency is different from the input frequency, frequency offset mode (option S93080A) must be used for this measurement.

Note: This measurement is made much easier if your VNA has the Frequency Converter Application

Equipment Setup

Example: A calibrated Conversion Loss (Down-converter) measurement

Swept Input with Fixed LO = Swept Output

- RF Input: 3.1 - 3.3 GHz
- LO: 2.2 GHz
- IF Output: 900 - 1100 MHz

VNA setup and calibrate on channel 1

1. On channel 1 create an unratioed R measurement over the ENTIRE input and output frequency span (.9 - 3.3 GHz). This will be the base source power cal that will be copied to the R and B channel measurements.

2. Perform a source calibration using a power meter. This makes the power level at the input of the mixer very accurate.

Setup Reference measurement on channel 2
1. **Copy channel 1** to channel 2 which will display the reference input to the mixer. The channel 1 source power cal is copied with the other channel settings.

2. Change measurement to R1 unratioed.

3. Change RF Input frequency to 3.1 - 3.3 GHz. The source power cal becomes interpolated.

4. Perform receiver power cal. Do not need to make physical connections. The VNA source is internally connected to the R1 receiver. Makes the R receiver read the source power level.

### Setup B measurement on channel 3

1. Copy channel 1 to channel 3. This channel will display the output of the mixer. The channel 1 source power cal is copied with the other channel settings.

2. Change measurement to B unratioed.

3. Change IF Output frequency to .9 - 1.1 GHz. This causes the source power cal becomes interpolated.

4. Connect thru line from port 1 to port 2.

5. Perform receiver power cal. This makes the B receiver read the source power at the IF Output frequencies.

6. **Turn OFF receiver power cal.** This prevents an error when changing to input frequencies (next step).

7. Change RF Input frequency to 3.1 - 3.3 GHz. This changes the channel back to the mixer RF Input frequencies.

8. **Enable Frequency Offset.**

9. Change Offset to (-2.2 GHz). This tunes the B receiver to the IF Output frequencies .9 to 1.1 GHz. **Note:** The minus sign indicates a down-converter measurement.

10. Turn ON receiver power cal.

### Measure the Mixer

1. Connect the mixer.

2. Adjust **scale** to suit your needs.

3. Enable **markers** to read power levels for each trace.

The display below shows:

- Ch3 B receiver (bottom trace) absolute output power.
Ch2 R1 receiver measurement (top trace) absolute input power to the mixer.

With this method, the conversion loss math (B/R1) can be performed with Equation Editor (not shown). The B/R1 ratio measurement is not supported with receiver power Cal turned on. However, conversion loss (C21) measurements can be made directly and are much easier using the Frequency Converter Application, FCA (Opt S93083A/B).
What is Conversion Compression?

Conversion compression is a measure of the maximum input signal level for which a mixer will produce linear operation. It is very similar to the gain compression experienced in amplifiers.

To understand conversion compression, you must first understand conversion loss. This is the ratio of the mixer output level to the mixer input level. This value remains constant over a specified input power range. When the input power level exceeds a certain maximum level, the constant ratio between input and output power levels begins to change. The point at which the ratio has decreased 1 dB is called the 1-dB compression point. This is illustrated in the graphic below.

Why Measure Conversion Compression?

...
Conversion compression is an indicator of the dynamic range of a device. Dynamic range is generally defined as the difference between the noise floor and the 1-dB compression point.

**How to Measure Conversion Compression**

The equipment and setup used to measure conversion compression are essentially the same as for measuring conversion loss and is illustrated in the following graphic.

The VNA performs a power sweep using **frequency-offset mode** and the resulting display shows the mixer's output power as a function of its input power. The 1-dB compression point (or others such as 3-dB) can be determined using markers.

![Diagram of VNA setup](image)

**Measurement Accuracy Considerations**

**Equipment Setup Considerations**

- The couplers in the VNA have very good directivity. If the return loss of the DUT is bad, the reflected signal gets sampled by the VNA and can result in errors. This relates to error in DUT gain. To increase the accuracy, an attenuator can be added between the VNA's source port and the DUT's input port. Normally a 6- to 10-dB attenuator is sufficient. Addition of this attenuator, however, decreases the available drive to the DUT.

- With high drive levels the VNA can be driven into compression resulting in measurement error. With excessive drive levels, the VNA can be damaged. Add an attenuator between the output of the DUT and the receiver input of the VNA to avoid these problems.

**Calibration Considerations**
Source power calibration can be used to provide a high level of accuracy for this measurement.
Isolation Measurements of Frequency Converting Devices

- What is Isolation?
- Why Measure Isolation?
- How to Measure Isolation

See other Frequency Converting Device Measurements

What is Isolation?

Isolation is a measure of the leakage, or feedthrough, from one port to another. The more isolation a mixer provides, the lower the amount of feedthrough. Isolation is measured at the same frequency as the stimulus, not the converted or shifted frequency. Therefore, Frequency Offset capability is not necessary for these measurements.

Three main isolation terms are of interest for mixer measurements:

- LO-to-OUT isolation ($V_{LO}$)
- LO-to-IN isolation ($V_{LO}$)
- IN-to-OUT feedthrough ($V_{IN}$)

Why Measure Isolation?

Any unwanted signal "leaking" through the device will mix with the desired output signal creating intermodulation products, adding to intermodulation distortion. These unwanted signals may be...
difficult to filter out.

**How to Measure Isolation**

Use the following setups to measure the isolation of a mixer:

Note the following:

- The Input to Output isolation is very dependent on the LO power level. Isolation should be measured with the LO power at its normal operating level.

- Each of the ports not being tested should be terminated with an impedance typical of actual operation. This may not always be the characteristic impedance, Z0 (usually 50 or 75 ohms). For example, if the OUT port of a mixer is intended to be directly connected to a filter, then this filter should be used when measuring the LO-to-IN feedthrough.

![LO-TO-IN ISOLATION](image)

**LO-TO-OUT ISOLATION**
Measuring Converters vs. Mixers

Measuring IN-to-OUT feedthrough of a converter is identical to that of a mixer. The IN-to-OUT feedthrough is generally very small for a converter due to the inclusion of an IF filter in the device. Because of this, the measurement may require the VNA to have increased dynamic range.

Measuring LO leakage (LO-to-OUT and LO-to-IN) of a converter requires a different technique because the LO port is typically not accessible:

- The VNA can be tuned to the frequency of the LO signal and either the OUT or IN port connected to the VNA receiver port. The VNA source port is not connected.

- A spectrum analyzer can be connected to either the OUT or IN port and tuned to the frequency of the LO
signal.
Harmonic Distortion

- What is Harmonic Distortion?
- Why Measure Harmonic Distortion?
- How to Measure Harmonic Distortion
- Measurement and Accuracy Considerations

See other Frequency Converting Device Measurements

What is Harmonic Distortion?

Harmonics are multiples of any signal appearing at the mixer input and also multiples of the LO input. The distortion of the mixer's output characteristics caused by these harmonics is referred to as harmonic distortion. Harmonic distortion is caused by non-linearities in the device.

Harmonics are NOT signals created by two or more signals interacting (mixing); these signals are known as intermodulation products, which result in intermodulation distortion.

Why Measure Harmonic Distortion?

- It can degrade the performance of devices connected to the output of the mixer.
- The harmonics can also mix with other signals present in the mixer, adding to the intermodulation distortion of the mixer.

How to measure Harmonic Distortion

The harmonics can be measured using the VNA with Frequency Offset (option 80). The frequency of the LO to the mixer is set to zero and multiplier of the RF input is used to set the IF frequency (the harmonic). The equipment setup is shown below.

Since harmonics are specified in dBc, the fundamental RF and both the second and third harmonics are measured and the differences calculated. Multiple channels can be used to do this.

1. Connect the equipment.
2. Setup the measurement for calibration. See also Measurement and Accuracy Considerations.
Use three channels and frequency offset mode:

Channel 1 = F1 to F2

Channel 2 = F1 to 2F2 (frequency offset mode, multiplier = 1)

Channel 3 = F1 to 3F2 (frequency offset mode, multiplier = 1)

- Perform a source power calibration and receiver power calibration over the entire frequency range. See Measurement and Accuracy Considerations.

- Reduce the frequency span and increase the frequency offset multiplier on Channels 2 and 3:
  Channel 2 = F1 to F2 (frequency offset mode, multiplier = 2)
  Channel 3 = F1 to F2 (frequency offset mode, multiplier = 3)

  **Note:** Because the frequency span has been changed from that used for calibration, the source and receiver calibrations will be interpolated.

- Connect the DUT, make the measurement, and calculate the harmonic response:
  Set up markers on Channels 1, 2 and 3, and determine the difference between the marker values to get the dBc value of each harmonic.

  Channel 1 - Channel 2 = 2nd harmonic (dBc)

  Channel 1 - Channel 3 = 3rd harmonic (dBc)

  **Note:** Be sure to set the markers to the appropriate stimulus. Channel 2 markers should be set to twice the frequency of Channel 1 markers. Channel 3 markers should be set to three times the frequency of Channel 1 markers.

---

**Measurement and Accuracy Considerations**

**Equipment Setup Considerations**

- A filter must be used at the input of the mixer to remove the VNA source harmonics.
Return Loss and VSWR

- What are Return Loss and VSWR?
- Why Measure Return Loss and VSWR?
- How to Measure Return Loss and VSWR

What is Return Loss and VSWR?

Return loss and VSWR are both linear reflection measurements, even when testing frequency conversion devices, because the reflected frequency is not converted. These measurements are essentially the same as for filters and amplifiers. Learn more about Reflection Measurements.

Why Measure Return Loss and VSWR?

Devices which have poor return loss and VSWR result in loss of signal power or degradation of signal information.

How to Measure Return Loss and VSWR

Setup the VNA measure return loss and VSWR as you would any two-port device. Connect your frequency converting device as shown in the following diagrams:

RETURN LOSS AND VSWR OF MIXER INPUT PORT
RETURN LOSS AND VSWR OF MIXER OUTPUT PORT

RETURN LOSS AND VSWR OF MIXER LO PORT
Gain Compression for Amplifiers GCA (Opt S9x086A 086)

Other VNA Applications
Features, Requirements, and Limitations

**Features**

- Fast, easy, and complete Gain Compression measurements for amplifiers.
- Many compression parameters to choose from, including gain, input power at compression, output power at compression, input match, and compression level.
- Several compression methods to choose from, including deviation from linear gain, deviation from max gain, back-off, and X/Y, and compression from saturation.
- Three acquisition methods to choose from: Power per Freq, Freq per Power, and SMART Sweep
- SMARTCal Calibration Wizard to guide you through Full 2-Port or Enhanced Response calibration, plus Source Power calibration.
- Compression Analysis allows traditional power sweep view at a selected frequency.
- Receiver Leveling provides continuous source power accuracy.
- Supports Wideband (NOT Narrowband) Pulse measurements using the new integrated Pulse setup dialogs.

**Requirements**

- Option S9x086A (software option only) must be enabled.
- When performing an optional calibration:
  - ECal module or Calibration Kit
  - Power meter/sensor

**Limitations with GCA**

- Number of points limited to 100,001 for two-dimensional acquisitions, 50,000 points for SMART Sweep.
- Standard CW power sweep is NOT supported in a Gain Compression channel.
- Independent IFBW, Power Levels, Shift LO, or Sweep Time in a segment table is NOT supported.
- Stepped sweep mode only.
- Linear, Log, and Segment frequency sweep modes only.

The following VNA Features are **NOT** Available in a Gain Compression channel:
• Unratioed receiver measurements (A, B, R)
• ECAl User Characterization
• Some Fixturing Features
• FOM or FCA
• External Test Set Control (Option S93551A/B)
• IF Path Configuration
• CW Time sweep
• Balanced measurements
• Save Auto Formatted Citifile data.
• Narrowband Pulse measurements using the Integrated Pulse App

Gain Compression Application Concepts

What is Gain Compression

An amplifier has a region of linear gain, where the gain is independent of the input power level. This gain is commonly referred to as small signal gain. As the input power is increased to a level that causes the amplifier to approach saturation, the gain will decrease. The 1 dB gain compression is defined as the input power level that causes amplifier gain to drop 1 dB relative to the linear gain.

You can quickly measure the gain compression using a compression marker on a power sweep trace.

Terms used in GCA

Linear Power Level  The specified input power that yields linear gain (also known as 'small-signal gain') in the amplifier.

Reference gain  The measured gain that is used as a reference for determining compression level. The
Compression Method that is used could cause this value to be different.

Compression level The specified amount of gain reduction from the reference gain.

Target gain The gain at the specified compression level. Although this term does not appear in GCA, it is important to understand when discussing the various compression parameters.

For example, when using Compression from Linear Gain method with the following settings:

- Linear gain (measured at Linear Input power) = 10.2 dB
- Compression level (specified) = 1 dB
- Target gain = 9.2 dB

This is called 'Target' gain because GCA will search for the closest measured gain to 9.2000 dB. It may not measure this gain exactly.

Compression point The operating point at which the measured gain is closest to the Target Gain. All compression parameters report data for this operating point.

Understanding the GCA Displayed Traces

One of the most important concepts to remember with GCA is that, each frequency data point represents many measurements using different input power levels.

Some things to notice about how GCA displays compression data:
1. The X-axis values are ALWAYS frequency. Imagine behind each frequency data point, a traditional power sweep curve with corresponding measurements and calculations to find the specified compression point.

2. The Y-axis values are always reported at the compression point. The value that is displayed depends on the compression parameter that you choose. The S-parameters that are displayed in a GCA channel are always measured at the linear and reverse power level.

Example: Five of the six GCA compression parameters are displayed in the above image. The missing trace, DeltaGain21 is discussed below.

- Markers are placed at 4.549 GHz for all of the parameters.
- Tr 3 CompIn21 (Input power at the compression point) shows the marker value to be \(-5.4117\) dBm. This is the power into the DUT that was required to achieve the compression point. Notice that this is about the same input power required to achieve the specified compression at ALL frequencies.
- Tr 5 CompGain21 (Gain at the compression point) shows the marker value \(9.6443\) dB. This is the measured gain at the compression point.
- To see the gain at a different input power at this frequency, use the Compression Analysis feature.

Create a GCA Measurement

1. Press Meas > S-Param > Meas Class....

2. Select Gain Compression, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.

Gain Compression Parameters

There are several Gain Compression parameters, as well as standard S-parameters and ADC parameters, that can be measured in a GCA channel.
How to add GCA Parameters

Using **Hardkey**/**SoftTab**/**Softkey**

1. Press **Trace**, then select trace.
2. Press **Meas**, then select a parameter.

Using a mouse

1. Click **Instrument, Trace, Add Trace**.
2. Click **Response, Meas**, then select a parameter.

### Programming Commands

#### Linear S-Parameters

For convenience, the standard S-parameters are offered in a GCA channel. S11 and S21 are measured at the specified Linear Input level. S22 and S12 are measured at the specified Reverse power level.

**Note:** When a **DC meter** is added, it will be displayed in the New Trace dialog and **SMART Sweep Safe Mode** dialog (in DC Parameters pull down menu).

<table>

#### ADC Parameters

Four ADC analog-to-digital converter measurements are offered in a GCA channel:

- **Al1** and **Al2** are measured at the specified Linear Input level.
- **CompAl1** and **CompAl2** are measured at the specified compression point.

These DC measurements, along with **Equation Editor**, allow you to make PAE measurements at the Linear Input level and compression point.

These measurements are made at pins 7 and 8 of the VNA **Power IO connector**.

Learn more about ADC measurements.

#### Compression Parameters
The following table assumes: DUT Input = VNA port 1 and DUT Output = VNA port 2.

When the Port mapping is different, the parameters in GCA are updated accordingly. For example, with Input = port 2 and Output = port 1, then "CompIn12" would be displayed.

The raw data for these parameters are always measured.

<table>

**Compression Methods**

GCA offers the following methods to find the compression point of an amplifier using GCA:

**Compression from Linear Gain**

The Reference Gain is measured using the specified Linear (Input) Power Level. The Target Gain is calculated as the Linear Gain minus the specified Compression Level. For example 8.3 dB - 1 dB = 7.3 dB.

**Compression from Max Gain**

The linear region of an amplifier gain may not be perfectly linear. The highest gain value that is found at each frequency is used as the Reference (S21) Gain. The Target Gain is found in the same way as Compression from Linear Gain.

**Compression from Saturation**

This method is used to better find the compression point when measuring amplifiers with non-linear gain as shown in the following image:
The Max power out value * is found at each frequency. Then input power is lowered until the output power decreases by the specified 'From Max Pout' value. This is the compression point.^

**Backoff and X/Y method**

These two compression methods are very similar.

- Both methods specify a difference in input power (X axis) between the linear region and compression point.
- For the Y-axis difference:
  - **Backoff method** specifies Compression Level which is a difference in **Gain**.
  - **X/Y method** specifies Delta Y which is a difference in **Output Power**.

GCA searches for these points differently for **2D sweeps** and **SMART sweep**.

The following images show how Backoff and X/Y method is calculated at ONE frequency.
The compression point (yellow circle) is where 10 dB more input power yields 1 dB less gain than at the reference point (blue circle).

---

Acquisition Modes

The GCA offers three modes for data acquisition: Two 2D sweep modes, and SMART sweep.

To see a traditional power sweep at a single frequency, use the Compression Analysis feature. Learn more.

2D (two-dimensional) Sweeps

This is the easiest method to understand, and the least efficient for finding the compression point. Both 2D sweep modes work as follows:

1. All GCA measurements begin by measuring S-parameters at the specified Linear Power level. Reverse parameters are measured ONLY if Full 2-port calibration is applied or if a reverse parameter is displayed. Learn more about Cal choices.

2. Gain measurements are then made at ALL of the specified frequency and power values. Although these are conceptually 2-Dimensional sweeps, a single sweep is constructed in firmware. See Data Points Limit.

3. After data has been measured, a search is performed to find the compression point. You can choose to interpolate between the two measured points closest to the target gain. Learn more.
As each sweep is performed, dots are plotted next to the Ch indicator in the lower left corner of the display to indicate progress for the current sweep.

**Note:** For Backoff and X/Y compression method, GCA does not verify that the specified Start - Stop power range is at least the size of the specified Backoff or X value. The closest compression point is always reported.

**Note:** SMU Hardware List trigger mode is NOT supported in GCA 2D sweeps.

### 2D Sweep Modes

- **2D Sweep Power per Frequency** - Input power is stepped from Start to Stop at each specified frequency. From the following example you can see that the device is exposed to the highest power level (p3) at the first frequency (f1). This could heat the device early in the measurement and affect compression results.

The following examples show (frequency, power) values for three frequency points and three power points, resulting in a total of 9 measurements:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>f1</td>
<td>f1,p1</td>
<td>f1,p2</td>
<td>f1,p3</td>
<td>f2,p1</td>
<td>f2,p2</td>
<td>f2,p3</td>
<td>f3,p1</td>
<td>f3,p2</td>
<td>f3,p3</td>
</tr>
</tbody>
</table>

- **2D Sweep Frequency per Power** - Frequency is swept from start to stop at each specified power level as follows:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>

<td>f1,p1</td>
<td>f2,p1</td>
<td>f3,p1</td>
<td>f1,p2</td>
<td>f2,p2</td>
<td>f3,p2</td>
<td>f1,p3</td>
<td>f2,p3</td>
<td>f3,p3</td>
</tr>
</tbody>
</table>

### Viewing and Saving 2D Data

It is NOT possible to plot ALL of the 2D measurement data on the VNA display. However, it can be saved to a *.csv file and then read into an Excel spreadsheet. The initial S-parameter measurement data is not saved to this file. Learn more.

You can also view on the VNA all power sweep information at a selected frequency using the Compression Analysis feature.

### SMART Sweep

SMART Sweep is usually the fastest and most accurate method to measure Gain Compression. Unlike the 2D acquisition modes which measure all of the specified frequency / power points, SMART Sweep performs a series of power search iterations. At each frequency, an 'intelligent guess' of input power is made to find the compression level that is within tolerance. This guess is further refined with each
successive power search iteration sweep.

SMART Sweep continues to iterate until one of the following conditions occur:

1. ALL data points are within tolerance. When the compression level for a data point achieves the specified tolerance, it continues to be measured and input power changed to improve the measurement within tolerance.

2. The specified compression level can NOT be achieved for the remaining frequencies that are not in tolerance. Either the Start power is too high or the Stop power is too low.

3. Maximum iterations have been achieved. If a measured gain is not within the specified tolerance before the specified Max number of Iterations has been reached, then the last power reading is used as the compression point.

The Iteration Counter, Dots, and Bangs(!)

Next to the Ch indicator, in the lower left corner of a GCA window, the following annotation appears:

- An iteration counter is incremented each time input power is adjusted.
- A dot appears when another 10% of the frequency points are within tolerance.
- ! (bangs) are displayed after the last iteration. Each bang represents 10% of the data points that are NOT within tolerance.

SMART Sweep and Compression Method

The intelligent guess process works differently depending on the compression method. This is important because Backoff and X/Y compression methods subject the DUT to significant changes in input power during an iteration sweep. This can affect the DUT and the measurement results.

Learn all about Backoff and X/Y compression methods.

ALL GCA measurements begin by measuring S-parameters at the specified Linear Power level. Reverse parameters are measured ONLY if Full 2-port calibration is applied or if a reverse parameter is displayed. Learn more about Cal choices.

- Backoff and XY Because both compression methods specify the separation between the "linear" region and the "compressed" region, each iteration requires a single sweep at two dramatically different power levels over the same frequency range. The first half of the sweep measures the DUT at the Backoff or X power level. The second half of the sweep measures the DUT at the compressed power level, specified by the Start
and Stop power range. At the beginning of the second half, the power level rises by the Backoff or X value. The specified Settling Time is applied at this point to allow the DUT time to react to this significant change in power level. Safe Sweep does NOT minimize this change in input power. However, Safe Sweep with Backoff and XY methods DOES prevent the DUT from being exposed to too much input power.

- **Compression From Linear Gain** After the reference gain is measured at the linear input power, the next iteration measures the DUT at a higher power level which attempts to push the DUT well into compression. Subsequent sweeps, depending upon the compression level of the DUT, either increases or decreases the power in order to reach the desired compression level. Usually, by the third iteration sweep, a curve-fit algorithm is utilized to precisely find the compression point.

**Note:** The DUT can be subject to significant changes in power from one iteration sweep to the next. This can be minimized by the use of SAFE Sweep and careful selection of the corresponding settings.

- **Compression from Max Gain** The maximum gain that is found at each frequency is stored and used to calculate the compression point. SMART Sweep does NOT perform extra iterations to search for the maximum possible gain of the amplifier at each frequency.

- **Compression from Saturation** The maximum power out that is found at each frequency is stored and used to calculate the compression point. SMART Sweep does NOT perform extra iterations to search for the maximum possible power out of the amplifier at each frequency.

**Using the Gain Compression Application**

The following is a general procedure for performing a GCA measurement. The challenge with GCA is configuring a measurement that yields the true compression performance of YOUR DUT. This requires knowledge of the Gain Compression settings and knowledge of the DUT.

See specific dialog boxes below.

1. Disconnect the DUT if preset or default power levels may damage the VNA or DUT.
2. **Preset** the VNA, or configure a suitable **User Preset** that will be safe in case the DUT is connected.
3. Create a GCA channel. Learn how. The default trace is S21.
4. Start **GCA Setup dialog** and configure the measurement settings based on the DUT, adapters, attenuators, booster amplifiers, and fixtures to be used in the measurement.
5. Save the **instrument state** (optional).
6. Connect DUT and apply bias and RF power as appropriate. The default measurement for a GCA channel is S21 (amplifier gain). Inspect the gain measurement to ensure the DUT is operating as expected.
7. Add GCA compression parameter traces. Learn how.

8. Adjust the measurement settings to yield satisfactory compression parameters. See GCA Measurement Tips.

9. Start and complete the GCA Calibration wizard.

How to start the Gain Compression Setup dialog

Using Hardkey/SoftTab/Softkey

1. Press Freq > Main > GCA Setup....

Using a mouse

1. Click Stimulus
2. Select GCA Setup...

Frequency tab - Gain Compression - dialog box help

Configures the frequency settings over which Gain compression is to be measured, as well as the measurement method.

Sweep Type

Choose a method in which to sweep frequency: Linear, Log, and Segment Sweeps. This setting applies to all data acquisition modes.
**Notes**

- Log and Segment Sweep are NOT available on GCX.
- CW Sweep is NOT available in GCA. However, to see a traditional power sweep at a single frequency, use the **Compression Analysis** feature.
- To use CW Sweep in GCX, set all ranges to **Fixed** on the **Mixer Frequency tab**. This has the same effect as setting all ranges to Start = Stop Frequency.

**Segment Sweep Notes (GCA ONLY)**

- The segment table shown on the dialog is **READ-ONLY**.
- Learn how to **Create and edit the Segment Sweep table**.
- **Independent IFBW** and **Power** are NOT available.
- **X-axis point spacing** is available beginning with A.09.10.

**Data Acquisition Mode**

Specifies HOW the gain compression data is collected.

**SMART Sweep**

- At each frequency, input power is 'intelligently' adjusted to find a measured gain equal to the target gain.
- Faster and more accurate than 2D sweeps to measure Gain Compression point at a number of frequencies.
- Learn ALL about SMART Sweep

**2D (two-dimensional) Sweeps**

- **Sweep Power per Frequency** Performs a series of power sweeps at each successive frequency.
- **Sweep Frequency per Power** Performs a series of frequency sweeps at each successive power level.
- Learn ALL about 2D sweeps

**Sweep Settings**

Click each to learn more about these settings.
- **Number of points** Number of frequency points to measure. The Frequency points may be limited due to the number of specified Power points. See Data Points Limit.

- **IF Bandwidth** Set this value to yield acceptable trace noise when measuring gain at the linear power level. This level of noise contributes directly to the accuracy of compression point. A lower value (narrower IFBW) allows for more accurate, but slower, measurements. See GCA Measurement Tips to see how to best set IFBW.

- **Start / Stop, Center / Span** frequencies. Set the frequency range over which to measure Gain compression.

### Data Points Limit

The maximum number of measurement data points depends on Acquisition method and Compression method as follows:

<table>
<thead>
<tr>
<th>Compression method</th>
<th>SMART sweep</th>
<th>2D sweep</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of frequency points is reduced to ensure the total number of data points does not exceed the specified limit. Frequency points = maxpoints/2.</td>
<td>Number of power points is reduced to ensure the total number of data points does not exceed the specified limit.</td>
<td></td>
</tr>
<tr>
<td>Data points = freq points</td>
<td>Data points = freq points</td>
<td>Data points = (freq. points) * (power points)</td>
</tr>
<tr>
<td>Max  = 100,001</td>
<td>Max  = 100,001</td>
<td>Max power points = 2,001</td>
</tr>
<tr>
<td>Data points = 2 * freq points</td>
<td>Max  = 100,001</td>
<td>Max data points = 100,000</td>
</tr>
<tr>
<td>Data points = freq points</td>
<td>Max  = 100,001</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** Although the dialog box will allow you to enter any number of frequency or power points, the values are checked when **OK** or **Apply** is pressed. If a limit is exceeded, the relevant data points are reduced to the maximum allowable number without warning.
Configures RF power and Power Sweep settings for Gain Compression measurement.

**Power ON (All channels)** Check to turn RF Power ON or clear to turn power OFF for all channels.

**Input Port**

Select the VNA port that is connected to the DUT Input.

**Linear Power Level** The input power that yields the linear gain of the DUT. The linear gain is used as the reference gain when calculating the **Compression from Linear Gain**. Input match is also measured at this power level.

**Source Attenuator** Specifies the attenuator setting associated with the port connected to the input of the DUT. This attenuator will affect the range of available power into the DUT. Learn more about Source Attenuation.

All VNA channels in continuous sweep must have the same attenuation value. Learn more.

**Receiver Attenuator** Specifies the attenuator setting for the receiver associated with the output of the DUT. When the power into the receiver test port is around +10 dBm, the VNA receiver may be in compression. However, with receiver attenuation, lower input power levels may become too noisy to make accurate power measurements. In this case, lower IFBW to reduce noise. Learn more about Receiver Attenuation. (This only applicable for PNA and M9485A)

**Source Leveling Mode** Specifies the leveling mode. Choose Internal or Receiver R1. Learn how to configure Receiver Leveling. Open Loop should only be used when doing Wideband Pulse
Output Port

Select the VNA port that is connected to the DUT Output.

Reverse Output Power  Sets power level into the output of the DUT for reverse sweeps. Port power is automatically uncoupled.

Reverse power is applied to the DUT ONLY under the following conditions. Otherwise, this setting is ignored.

- When Linear Output Match or Linear Reverse Isolation parameters are requested.
- When Full 2-port correction is used. You can perform a full 2-port cal and downgrade to an Enhanced Response Cal to prevent reverse power from being applied to the DUT. Learn more.

Source Attenuator  Specifies the attenuator setting for the port connected to the DUT output. This setting will affect the range of available power at the DUT output port.

  Auto  - Selects the proper attenuation setting automatically.

Receiver Attenuator  Specifies the attenuator setting for the receiver associated with the DUT output port. (This only applicable for PNA and M9485A)

Source Leveling Mode  Specifies the leveling mode. Choose from: Internal (normal operation) or Open Loop (used only for Wideband Pulse measurements).

Power Sweep

Power Points  Number of power points to measure for 2D acquisition modes. The Power Points may be limited due to the number of frequency data points. See Data Points Limit. This setting is NOT available in SMART Sweep, which uses only enough power points to find the specified compression level.

Start and Stop Power

- 2D sweep  In Backoff, X/Y, and Compression from Max Gain methods, sets the range of power levels that are applied to the DUT to find BOTH the Reference Gain and Compression point. Make sure this range is wide enough to include both. For example, if the Backoff level is 10 dB, then the power range must be greater than 10dB. Otherwise, GCA will report a compression value using the closest reference gain and compression point, which may be inaccurate. In Compression from Linear Gain, the reference gain is measured at the Linear...
Power Level, so the Start and Stop power levels are used to find the compression point.

- **SMART sweep** Sets the range of power over which GCA will search for the compression point. The reference gain is found using the Linear Power Level, Backoff, and X values, depending on the Compression Method. To reduce the number of iterations that are required to find the compression point, limit the Start / Stop power range to the input levels that will achieve compression. Do not include the linear region.

**Note:** If your DUT requires more input power to achieve compression below 3.2 GHz, use the PNA-X Hi-power mode, available from the RF Path Configuration dialog. The disadvantage to this is higher harmonic content.

**Power Step (Size)** Calculated value from current Start, Stop, and Points settings. This setting can NOT be changed directly.

**Path Configuration** click to launch the RF Path Configuration dialog.

---

**Compression tab - Gain Compression** dialog box help

**Compression Method**

Learn ALL about these Compression Methods

- **Compression from Linear Gain** The specified compression **Magnitude Level** is measured from the linear gain. The linear gain is measured using the **Linear Input Power** that is specified on the **Power tab**.
• **Compression from Max Gain** The specified compression level is measured from the maximum gain level. In SMART sweep, the Max Gain value is updated as each iteration occurs. To increase the chances of measuring the actual maximum gain of the amplifier, **Safe Sweep** should be invoked using low Coarse and Fine increments.

• **Compression from Back Off** This compression method uses the Compression Level and Back Off values for finding the compression point.

• **X/Y Compression** This compression method uses the specified parameters (X and Y) as the criterion for finding the compression point.

• **Compression from Saturation** Similar to Compression from Max Gain, except the specified compression level is measured from the maximum power out level. Use this method to better find the compression point when measuring amplifiers with non-monotonic gain. In SMART sweep, the Max power out value is updated as each iteration occurs. To increase the chances of measuring the actual maximum power out of the amplifier, **Safe Sweep** should be invoked using low Coarse and Fine increments.

**Phase**

When **Compression from Linear Gain** is selected and the **Data Acquisition Mode** in the Frequency tab is set to **Sweep Power Per Frequency (2D)** or **Sweep Frequency Per Power (2D)**, the following Phase functions are enabled.

• **Magnitude Only** Measures compression against magnitude.

• **Phase Only** Measures compression against phase.

• **Magnitude or Phase** Measures compression against magnitude or phase.

• **Phase Level** Specifies the phase to interpolate compression point.

• **Phase Details...** Accesses the Advanced Phase Settings dialog.

**Gain Compression Measurement Class Dialog**

![Advanced Phase Settings](image)
Gain Compression Converters Measurement Class Dialog

Compute Linear Power from Percent of Span Specifies the aperture as a percentage of span to compute linear input power.

Smooth Power Sweep Using Enables the power sweep to be smoothed.

Aperture Aperture used for smoothing the power sweep.

Use Reference Mixer Enables a reference mixer. To improve the noise of the phase measurements in Gain Compression Converters (GCX), an optional user supplied external reference can be added to the R1 loop. The LO for the reference mixer should be common with the LO for the DUT mixer. After this hardware is added, and this function is enabled, the GCX application will use the reference mixer to improve the phase measurements.

Force Source Power Out Port 1 This function is used when GCX channels with a reference mixer and one GCA channel without a reference mixer are set up simultaneously and you want to use the same path configuration for all channels. This remaps the source port to Port 1.

SMART Sweep

Learn ALL about Smart Sweep.

Tolerance Specifies an acceptable range for measuring the compression level. Reducing this value can significantly increase the number of iterations that are required to find the compression point.

Maximum Iterations Specifies the maximum number of power search iterations SMART Sweep
is allowed. Reducing this value can cause SMART sweep to terminate before all compression levels are found to within the specified tolerance.

**Show Iterations**  When checked, the compression parameter traces are updated at the completion of each power search iteration. When cleared, compression parameter traces are updated when SMART Sweep completes the power search iteration process.

**Read DC at Compression Point**  When checked, only the DC readings at the compression point in the last iteration of a smart sweep will be taken. By default, the DC traces are read at each point in the sweep. In some cases, the user may only want to read the DC meter at the compression point to improve measurement speed.

---

**2D Sweep - Compression Point Interpolation**

When a 2D Sweep is selected (on the Frequency tab), check this box to calculate and display interpolated compression traces.

The **Target gain** is calculated using a complex linear ratio between the two closest measured values. All compression parameters are then interpolated using this same ratio.

Clear the box to display compression parameters for the closest compression point, either high or low, to the level specified in the Compression Method setting.

**End of Sweep Condition**  Specifies the power level applied to the DUT at the completion of a GCA measurement.

GCA performs numerous power and frequency sweeps on the DUT during the overall measurement process. This setting has no affect on these intermediate sweeps. This setting only applies at the end of the very last sweep in the GCA channel.

In addition, this setting applies ONLY to the GCA channel. All other channels operate independently of this setting. Therefore, the power applied to the DUT after all channels have been measured may be different from this setting.

Choose from:

- **Default**  Use the default VNA method.  Learn more.
- **RF OFF**  RF power is turned off when GCA completes a measurement cycle.
- **Start Power**  RF power is set to the start power level.
- **Stop Power**  RF power stays at the stop power level.

**Settling Time**
Used ONLY in SMART Sweep when Back Off or X/Y compression algorithms are selected.

This setting allows additional dwell time when the input power changes from the back-off level to the compression level. Learn more.

**SMART Sweep Safe Mode** dialog box help

For use with SMART Sweep ONLY.

When enabled, Safe Sweep increases the input power to the DUT by the specified amounts, allowing the compression point to be achieved gradually. While this will increase the number of iterations required to achieve compression, it also minimizes the possibility of driving the DUT too far into compression.

**Note:** Safe Sweep does **NOT** minimize the dramatic change in input power with Backoff and XY method. However, Safe Sweep with Backoff and XY methods **DOES** prevent the DUT from being exposed to too much input power. Learn more.

**Safe Mode (Enable)** Check to enable Safe Sweep.

**Coarse Increment** Sets the maximum change in input power, up or down, which will be applied to the DUT from one iteration to the next. Default = 3.0 dB.

Without Safe Sweep, the maximum change in input power can be the entire Backoff or X value when using these compression methods.

**Fine Increment** Once the Fine Threshold has been achieved, this becomes the maximum change in input power, up or down, which will be applied to the DUT. Default = 1.00 dB

**Fine Threshold** Specifies the compression level in which Safe Sweep changes from the COARSE to the FINE increment. Default = 0.5 dB. This means that, by default, the VNA uses the Fine Increment adjustment when compression reaches 0.5 dB.
**Max Output Power** To protect the VNA from damage, when the VNA port that is connected to the DUT Output measures the specified value, the input power to the DUT is no longer incremented at that frequency. In these cases, the compression point would probably not be achieved.

**DC Parameters** Select a DC device from the pulldown list. (Modification Distortion Only)

*Note:* When a DC meter is added, it will be displayed in the New Trace dialog and SMART Sweep Safe Mode dialog (in DC Parameters pull down menu).

**Max DC Power** Enter the limit value of the DC device. When the Max DC Power is above the limit value, the power sweep is clipped and returns to the previous safe value. The units are changed automatically per the Type setting in the DC meter dialog. (Modification Distortion Only)

---

**Compression Analysis**

Compression Analysis changes the current trace into a power sweep trace at a specified CW frequency. The current parameter and acquisition method is unchanged. For example, with a CompGain21 trace displayed and SMART Sweep selected, enable Compression Analysis. The trace becomes a power sweep trace at the specified CW frequency. The Y-axis displays S21 Gain at each X-axis power point.

When Smart sweep is used, a complete power sweep is not performed, but only the data points that are required to find the compression point. To see a traditional power IN vs power OUT compression sweep, use one of the 2-D acquisition methods.

You can create PNOP or PSAT markers on a CompOut trace with Compression Analysis mode ON. Learn more.

---

**How to perform Compression Analysis**

With any compression parameter (such as CompGainS21) displayed:

**Using Hardkey/SoftTab/Softkey**

1. Click **Math > Analysis > Compression Analysis**....

**Using a mouse**

1. Click **Response**
2. Select **Math**
3. Select **Compression Analysis**
Notes: When an S21 or S11 trace is active, any compression parameter (such as CompGainS21) must also be displayed.

Compression Analysis is NOT allowed for S12 or S22 traces.

Scroll up to learn more about Compression Analysis.

Analysis Frequency: CW  Enter a frequency to use for the compression analysis trace.

Compression Analysis  Check to perform compression analysis. A compression trace is displayed at the Analysis (CW) Frequency.

Use Discrete Frequencies  Check to allow Analysis Frequencies at only the discrete points where data is measured. Clear to allow Analysis CW Frequencies that are interpolated from the data points. Then select ANY CW frequency between the start and stop frequencies of the GCA channel.

X-Axis

- Use Measured Pin  The X-axis displays the actual power that is applied to the DUT after match correction and R-channel drift correction.

- Use Source Pwr Settings  The X-axis displays the power level of the stimulus.

Saving GCA Data

Beginning with VNA release A.08.20, GCA data can be saved to a *.csv file in both 2D and SMART Sweep modes (previously only 2D modes). Also, a Delta Gain, AI1, and AI2 columns have been added.
to the data. Learn about ADC parameters.

How to save GCA data

With a GCA Compression trace active:

Using Hardkey/SoftTab/Softkey

1. Press Save Recall > Save Other > Save Data...
2. File Type= CSV Formatted Data (*.csv).

Using a mouse

1. Click File
2. Select Save Data
3. File Type= CSV Formatted Data (*.csv).

Notes

- This data type can be read by spreadsheet programs, such as Microsoft Excel.
- Data from the last complete sweep is saved to the specified *.csv file.
- If calibration is turned ON when the file is saved, then all data is calibrated. Otherwise, raw data is saved.
- All *.csv data saves include a reference power level sweep at the beginning of each frequency data.

SMART Sweep data with 5 iterations and 3 frequency points. The yellow highlight is added here for readability.

When saving or recalling 2D data:
- When Linear Input Power EQUALS Start Power, then the number of data points (rows) / freq = num power points.

- When Linear Input Power does NOT EQUAL Start Power, the number of data points (rows) / freq = num power points + 1.

- Make these selections on the GCA/GCX Power tab dialog.

GCA Measurement Tips

There are many settings in the Gain Compression Application. Here are a few tips when using GCA to learn as much as possible about the compression characteristics of your DUT in the most efficient manner.

DUT Compression Characteristics and GCA

Although GCA provides excellent results with a wide variety of amplifiers, it works best with amplifiers which have a monotonic compression curve. In some cases where the compression curve is not monotonic, for example if the amplifier gain expands before it compresses, the correct compression level may not be found.

To help a SMART sweep find the correct compression point, limit the Start and Stop power levels around the anticipated compression point. Learn more.

The following two power-sweep traces are examples of non-monotonic gain:

![DeltaGain Graph](image-url)
A DeltaGain trace is the best way to see how closely GCA is actually measuring to the desired compression level. In addition, you can view the phase of DeltaGain to see the phase deviation between the compressed gain and the reference gain. DeltaGain is calculated as:

- \[ \text{DeltaGain} = \frac{\text{Measured Gain (watts)}}{\text{Ref Gain (watts)}} \]
- In LogMag format: \[ \text{DeltaGain} = \text{(Measured Gain)} - \text{(Ref Gain)} \]

With SMART Sweep, DeltaGain (in LogMag format) shows how soon certain frequencies achieve the specified tolerance. Learn more.

Some other settings which may be helpful:

- Trigger source: Manual allows you to analyze data and make adjustments while allowing the device to cool.
- Construct Limit Lines around the compression point at the tolerance level.

The following image shows a DeltaGain21 trace using SMART Sweep. The Limit Lines were added manually.

In the above image:
### Relevant Settings

<table>
<thead>
<tr>
<th>Method = Compression From Linear Gain</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compression level = 1</td>
</tr>
<tr>
<td>Iteration Tolerance = 0.05 dB.</td>
</tr>
<tr>
<td>Maximum Iterations = 10</td>
</tr>
</tbody>
</table>

### Displayed Results

- A data point on -1.00 indicates that, at that frequency, the exact compression level (1 dB) was measured.
- Several frequencies did not achieve the specified tolerance (0.05 dB) before the Max Iterations (10) was reached.
  - **FAIL** and red data points outside the limit lines.
  - Nine dots (....) indicate that 90% of the data points achieved the specified compression level.
  - **one !** indicates that 10% of the data points did not achieve compression.
  - Learn more about the Iteration Counter and annotation.

### SMART Sweep Tips

- Compression from Linear Gain is the easiest compression method to understand and control in SMART Sweep. Learn more.
- If SMART Sweep requires more than twenty iterations, this is an indication that something is wrong. Try changing the Tolerance setting, Frequency Range, Start / Stop power range, IF bandwidth, or Dwell Time.
- If the number of iterations required to achieve the desired compression level changes significantly from one set of measurements to the next, this could be due to other effects, such as heating. Try increasing the dwell time or using a wideband pulse measurement configuration.
- If the DUT should not be significantly overloaded into compression, or the changes in the input power should be limited, use Safe Sweep mode with Deviation from Linear Gain compression method.

### Single Frequency Macros

**Note:** Beginning with VNA rev. A.09.00, the Compression Analysis feature provides an easier method of viewing a traditional power sweep at a single frequency than the GCA macros. However, the Macros are still maintained on the VNA hard drive.

The macros perform a single power sweep on the DUT using a standard channel with corresponding stimulus settings. The macro can show measurement differences from the compression analysis traces.
due to bias/thermal/settling effects of the DUT. So, the macro can help confirm a DUT is exhibiting some type of settling behavior which will need to be handled in some way.

Also, the macro is a great GCA programming example.

With a 2D sweep (NOT SMART Sweep) a script that is stored on the VNA hard drive automatically creates a traditional power sweep measurement in a standard channel using the same stimulus setting as the GCA channel. Use a marker in the GCA channel to specify the frequency for the measurement.

The script has two modes of operation:

1. **View Mode** displays all of the previous 2D sweep data at that frequency.

2. **Measure Mode** performs a new measurement at that frequency.

Both modes create a new S-Parameter channel using the same stimulus settings as the GCA channel, including port power, attenuator, IF Bandwidth, and dwell settings. The new channel does not support calibration or pulse characteristics.

To see noise on a measurement, use the **Measure** macro in continuous sweep. Adjust the IFBW and averaging until the noise versus sweep speed meets your needs.

To see other effects of your DUT at a specific frequency, use the **View** macro and the **Measure** macro with 2D sweep mode. Both macros present data using a standard channel. The View macro shows 2D data at a specific frequency, while the Measure macro shows freshly-measured data at the same frequency. Ideally, the data from these two would be identical. However, changes in your DUT behavior due to heating or other effects can cause these to be different. If significant differences exist, try:

- Using the 2D Frequency per Power setting rather than Power per Frequency
- Adjusting the dwell time
- Adjusting IFBW
- Use a wideband pulse configuration

**How to setup the Macros**

Each macro must be setup separately.

1. Press **Macro** > **Key Setup** > **Macro Setup**.

2. Select a blank line, then click **Edit**.
3. In **Macro Title**, type a short description such as Meas GCA or View GCA.

4. Click **Browse**, then navigate to C:\Program Files(x86)\Keysight\Network Analyzer\Applications\GCA\GCA.vbs

5. In Macro run string parameters:

   1. Type **M** for the Measure macro or **V** for View macro.
   
   2. Optional: Supply the following additional parameters in any order:

      - To run the program from a remote computer, specify the full computer name of the VNA.
      
      - Channel in which to create the measurement. If not specified, Measure is created in Ch30 and View is created in Ch31.

      - Example: Run string parameters for the Measure macro run from a remote computer in Channel 5.----M MyVNA 5.

6. Click **OK**.

**How to run the Macros**

On a GCA channel:

1. Create a 2D sweep. Either Power per Freq or Freq per Power. Both macros always create a power sweep at the frequency of interest.

2. Create a CompIn trace.

3. On the CompIn trace, right-click and select **Add Marker**. Drag the marker to the frequency of interest.

4. Press **Macro**, then select either by the short description your provided in Step 3.
Gain Compression is measured on Converters in the same manner as it is measured in Amplifiers. Also, the Mixer/Converter setup is very similar to that of SMC (Scalar Mixer Converter application).

In this topic (unique for GCX):

- Requirements and Limitations
- Using GCX
- Create a GCX Measurement
- Valid Mixer Configuration / Sweep Type Combinations
- Measurement Parameters offered in GCX
- GCX Calibration

The following Gain Compression for Amplifiers information is relevant for learning about GCX:

- Gain Compression Concepts
- Understanding the GCA Displayed Traces
- Compression Methods
- Acquisition Modes
- Compression Analysis
- Saving GCA Data
- GCA Measurement Tips

The following dialog setup tabs are shared with other applications:

- Frequency tab (GCA topic)
- Power tab (GCA topic)
- Compression tab (GCA topic)
  - Safe Sweep Mode dialog (GCA topic)
Requirements and Limitations

GCX requires Option S93086A/B (Gain Compression).

Limitations:

- Number of points limited to 100,001 for two-dimensional acquisitions, 50,000 points for SMART Sweep.
- Linear and CW sweep ONLY - No Power, Log, or Segment sweep. Learn more.
- GCX does NOT provide any built-in image rejection techniques. You should provide image rejection hardware if necessary.
- Stepped sweep mode only.
- Does NOT support Narrowband Pulse measurements using the integrated Pulse setup dialogs.

The following VNA features are NOT available with Gain Compression on Converters:

- ECal User Characterization
- Time Domain
- Balanced measurements
- Save Formatted Citifile data.
- Save SnP data.
- Port extensions
- Some Fixturing Features
- External Test Set Control (Option S93551A/B)
- Integrated Narrowband or Narrowband Pulse App
- Independent IFBW, Power Levels, or Sweep Time in a segment table is NOT supported.
**Using GCX**

The following is a general procedure for performing a GCX measurement. The challenge with GCX is configuring a measurement that yields the true compression performance of YOUR DUT. This requires knowledge of the Gain Compression and Mixer settings, and knowledge of the DUT.

See specific dialog boxes below for details.

1. Disconnect the DUT if preset or default power levels may damage the VNA or DUT.
2. **Preset** the VNA, or configure a suitable **User Preset** that will be safe in case the DUT is connected.
3. Create a GCX channel. **Learn how**. The default trace is SC21.
4. Start the GCX Setup dialog and configure the measurement settings based on the DUT, adapters, attenuators, booster amplifiers, and fixtures to be used in the measurement. To start the dialog, click **Stimulus**, then **Frequency**, then **GCX Setup**. **Learn about the setup dialogs**.
5. Save the **instrument state** (optional).
6. Connect the DUT. Inspect the measurement to ensure the DUT is operating as expected.
7. Add GCX compression and mixer parameter traces. **Learn more**.
8. Adjust the measurement settings to yield satisfactory compression results. **See GCA Measurement Tips**.
9. Start and complete the **GCX Calibration wizard**.

**Create a GCX Measurement**

1. Press **Meas** > **S-Param** > **Meas Class**....
2. Select **Gain Compression Converters**, then either:
   
   - **OK** delete the existing measurement, or
   
   - **New Channel** to create the measurement in a new channel.

3. A default SC21 measurement is displayed. To select additional parameters to display, press **Trace**, select a trace, press **Meas**, then select a parameter. **Learn more about GCX Parameters**.
How to start the Gain Compression for Converters Setup dialog

Using **Hardkey/SoftTab/Softkey**

1. Press **Freq > Main > GCX Setup...**

Using a mouse

1. Click **Stimulus**
2. Select **GCX Setup...**

**Programming Commands**

Valid Mixer Configuration / Sweep Type Combinations

The following are the **Valid Sweep Type / Mixer Configurations**.

<table>
<thead>
<tr>
<th>Sweep Type</th>
<th>Input</th>
<th>LO</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear</td>
<td>Swept</td>
<td>Fixed</td>
<td>Swept</td>
</tr>
<tr>
<td></td>
<td>Swept</td>
<td>Swept</td>
<td>Fixed</td>
</tr>
<tr>
<td>CW</td>
<td>Fixed</td>
<td>Fixed</td>
<td>Fixed</td>
</tr>
<tr>
<td></td>
<td>Fixed</td>
<td>Swept</td>
<td>Swept</td>
</tr>
</tbody>
</table>

For determining a valid mixer configuration with 2 LOs, one Fixed LO and one Swept is equivalent to having a single-stage Swept LO.

If you create an invalid Sweep Type / Mixer Configuration, a red message appears like the following:

**ERROR: Input range must be swept in Linear sweep mode.**

If this occurs, change the **Sweep Type** on the **Frequency tab**.

See other rules for configuring a mixer.

**GCX Measurement Parameters**

**Note:** The following table assumes: DUT **Input** = VNA **port 1** and DUT **Output** = VNA **port 2**.

When the Port mapping is different, the parameters in GCX are updated accordingly. For example, with Input = port 2 and Output = port 1, then "CompIn12" would be displayed.
<table>

**GCX Setup Dialogs**

All of the GCX Setup tabs are shared with other applications.

- Frequency tab
- Power tab
- Compression tab
  - Safe Sweep Mode dialog
A GCX Cal is conceptually the same as a Gain Compression Calibration. This includes the ability to perform or downgrade to an Enhanced Response Cal. Learn how.

The following Guided Cal Wizard pages are unique to GCX:

**GCX Calibration Setup** dialog box help

- **Waveguide/In-fixture/On-Wafer Setup** Starts the following dialog box.

- **Independent power cals for input and output ports (no thru)** Check if a Thru standard is NOT available. During the power cal, you will be prompted to connect the power sensor to the Input, then the Output port.

**Additional Power Cal Steps**

- **Enable LO1 / LO2 Power Cal** Check when LO1 / LO2 is controlled (on the Mixer Setup tab) to perform a Power Cal on the source.

**Note:** Phase Correction is NOT allowed for GCX measurements.
Waveguide/In-fixture/On-Wafer Setup dialog box help

This dialog box appears ONLY if you checked the Waveguide/In-fixture/On-Wafer Setup box in the previous Cal Setup dialog.

Allows you to embed or de-embed circuit networks on the input and output of your mixer under test.

For Network1 (Input) and Network2 (Output) select Embed, De-embed, or None.

Browse  Click to navigate to the .S2P file that models the network to embed or de-embed.

To Embed or De-embed

- **De-Embed** when there is a 2-port network that needs to be connected during the measurement, but it is NOT present during the calibration. An example might be when you do not have standards for a characterized test fixture, so you calibrate without the fixture, and make measurements with the DUT in the fixture. De-Embedding during the calibration extends the calibration reference plane to include the 2-port network.

- **Embed** when there is a 2-port network that to be disconnected during the measurement, but is present during the calibration. An example might be when a characterized adapter is required during the calibration but NOT present during measurements of the DUT. Embedding during the calibration retracts the calibration reference plane to exclude the 2-port network during the measurement.

Notes

- The S2P file for Network1 (on the input of the mixer), must cover the Input frequency range. The S2P file for Network2 (on the output of the mixer), must cover the Output frequency range.

- The frequency range of the S2P file must be the same, or larger than, the frequency range of the measurement. If more frequencies are included in the file, and the data points do not exactly match those of the measurement, interpolation will be performed.

- As in the image on the dialog (above), in all cases:
  - Port 1 of each network is assumed to be connected to the VNA.
  - Port 2 of each network is assumed to be connected to the DUT.
Select DUT Connectors and Cal Kits dialog box help

Allows you to specify the connector type and Cal Kit for each DUT port.

**Port n**  For each listed VNA port, specify the DUT connector type and gender, and the Cal Kit to use.

**input pwr sensor**  Specify the connector type of the power sensor. Select **Ignored** to not compensate for the effects of the adapter that may be necessary to connect the power sensor to the input reference plane.

**output pwr sensor**  Available when **Independent power cals for input and output ports** is checked on the GCX Calibration Setup dialog. Specify the connector type of the power sensor. Select **Ignored** to NOT compensate for the effects of an adapter that may be necessary to connect the power sensor to the output reference plane.

**De-embed input power sensor adapter**  Check to measure, then remove the effects of the adapter that is used to connect the power sensor to the calibration reference plane.

**Source Cal Settings**  Click to start the Source Cal Settings dialog. These settings allow you change ALL Source Cal and Power Meter settings.

**Note:** If your DUT connectors are:

- **Waveguide**  Change the system impedance to 1 ohm before performing a calibration. See **Setting System Impedance**.
- **Not listed** (male and female)  Select **Type A** as the connector type. Type A requires a calibration kit file containing the electrical properties of the standards used for calibration (see **Calibration kits**).
- **Unspecified** (like a packaged device)  Select **Type B** as the connector type. Type B requires a calibration kit file containing the electrical properties of the standards used for calibration (see **Calibration kits**).

**Modify Cal**  Check, then click Next, to start the Modify Frequency Cal dialog.
Gain Compression Calibration

The GCA Calibration Wizard guides you through a calibration of GCA or GCX channel. The procedure is the same regardless of the Gain Compression Settings. Option 086 or S9x086A/B is required.

- A Source Power Calibration is performed first.
- Then, your choice of a Full 2-port Cal or an Enhanced Response Cal.

How to start a GCA Calibration

Using Hardkey/SoftTab/Softkey

1. Press CAL > Main > Smart Cal....

Using a mouse

1. Click Response
2. Select Cal
3. Select Smart Cal...

Overview - GCA Source Power Cal

The GCA Calibration Wizard first performs a Source Power Cal. The GCA Source Power Cal is a little different from a standard Source Power Cal. Although GCA measurements are performed at many power levels, the GCA source power cal is performed at a single power level over the specified frequency span of your GCA measurement. The required source correction from that single power level is applied to ALL power levels. This method ensures that the 'absolute' power level being applied to the DUT is within the PNA-X source power linearity specification.

Although it is important for GCA to be able to set the absolute power level to the DUT, it is MOST important to be able to exactly measure the actual incident power. Therefore, during the GCA Source Power Cal, a receiver calibration is applied to the port 1 reference receiver, and indirectly to both test port receivers during the S-parameter calibration, correcting for impedance mismatch between the
power meter and the VNA source, and the DUT and the VNA source.

Although the cal process is also at a single power level, the dynamic accuracy of the PNA-X receivers is typically about +/- .05 dB, which is comparable to the accuracy of Keysight's best power sensors. This allows GCA to very accurately measure and report ALL power levels that are actually applied to the DUT.

**Full 2-port or Enhanced Response (ER) Cal**

By default, a full 2-port calibration is performed as part of a GCA and GCX calibration. However, you can change to an Enhanced Response Cal. The following issues may help you decide between these two Cal types:

- **Accuracy** A full 2-port correction is more accurate than ER when GCA measures linear gain. However, for non-linear measurements, ER yields identical compression values as a full 2-port cal, so this may not be a significant factor.

- **Measurement speed** An ER correction only requires measurements in the forward direction. The reverse parameters (usually S22 and S12) are not measured unless requested. With a full 2-port cal applied, all four S-parameters are measured, which requires an additional reverse sweep. Learn more.

- **Ease** A full 2-port cal is easiest with an ECal module. An ER Cal requires a Defined Thru or a Flush Thru Cal method. If these are possible, then an ER cal is easiest when using a mechanical Cal Kit.

- **High power** The test port damage level of a standard PNA-X is +30 dBm. Therefore, external attenuation may be required on the output of high power amplifiers, which degrades calibration accuracy for reverse (full 2-port) measurements. In addition, the external attenuation improves the DUT output / load match error, which allows a better uncorrected response and makes an Enhanced Response Cal the better choice.

- **DUT limitations** With an ER Cal applied, reverse measurements on the DUT are not performed unless requested.

**How to select Enhanced Response Cal**

At the Select DUT Connectors page of the GCA Cal Wizard:

1. Check **Modify Cal**, then click **Next**.
2. A Defined Thru or a Flush Thru Cal method must be selected.
3. Click **Cal Type/Std**s
4. Under Calibration type, select **EnhResp** (2 <= 1 refers to the receive port 2 and source port 1).

**Downgrade a Full 2-port Cal to Enhanced Response Cal** if you prefer to perform a Full 2-port cal, but not perform reverse sweeps on the DUT.
To change the correction on the channel from Full 2-port to Enhanced Response:

1. Press **CAL > Main > Correction Methods.**
2. Select **GCA EnhResp**, then **OK.**

![Select Calibration Type]

**GCA Cal Wizard**

![Select DUT Connectors and Cal Kits - GCA Cal dialog box help]

**Select DUT Connectors and Cal Kits - GCA Cal dialog box help**

This is a **standard Cal Wizard** page except for the following:

**Power Sensor** Specify the connector type and gender of the power sensor. When the power sensor connector is not the same type and gender as the DUT Port 1 connector, then an adapter is required to connect the power sensor to the port 1 reference plane during the Source Power Cal. An extra 1-port cal is performed to measure and correct for the adapter. No characterization S2P files are required.

- Select **Ignored** (at the bottom of the DUT Connectors list) to NOT compensate for the adapter.
- Select the Cal Kit that will be used for that process.

**Modify Cal** Check, then click **Next**, to Modify Cal (Standards AND Thru Method).
Source Cal Settings  Click to launch the Source Cal Settings dialog.

Learn more about GCA Source Power Calibration

---

**Gain Compression Calibration Step 1** dialog box help

**Power Level** at which to perform the Source Power Cal.

It is usually best to perform the Source Power Cal at 0 dBm because the power sensor is calibrated at that level.

However, if the Gain Compression measurement is performed entirely below or above 0 dBm, then perform the Source Power Cal at the **Stop** power which probably has the lowest level of measurement noise.

Learn more about GCA Source Power Calibration

The remaining Gain Compression Cal dialogs are the same as the standard SmartCal dialogs.

Return to [Gain Compression Application](#).
**iTMSA (Integrated True Mode Stimulus Application)**

This application is integrated into the VNA firmware as **S9x460A/B**.

- Features, Requirements, and Limitations
- True Mode Stimulus Concepts
- Using iTMSA
  - Create a Measurement
  - Set Power Level
  - Calibrate
  - Ratioed Receiver Measurements
  - Differential Input and Output Power Measurement

### Other VNA Applications

**Important Note**

When the first iTMSA measurement is created, an IFMUX Cal is performed, which takes a couple of minutes.

When finished, **Exit** then **restart** the VNA App.

If an IF board is replaced, this Cal should be performed again. To make this happen, delete `c:\users\public\network analyzer\IFMUX.txt`. When the next iTMSA measurement is created, the file will be recreated with new data.

### Features, Requirements, and Limitations

**Features**

- A seamless extension of existing VNA Balanced Measurement, but with True Mode stimulus.
- True Mode Stimulus measurements are performed in a standard S-parameter channel.
Requirements

- PNA-X and VNA (N522x) 4-port models
- Opt S9x460A/B (software option only); must be enabled.

Limitations with iTMSA

- Direct Receiver Access configuration of the front-panel loops is NOT allowed. This bypasses the coupler making it no longer possible to perform return loss measurement of the DUT (needed to align the two sources). However, inserting amplifiers or other components into the standard source path configuration at the front-panel loops IS allowed.
- Reversing the port couplers is NOT recommended due to the increased noise on the initial sweep for match correction. Good reflection measurements on all four ports is necessary to ensure adequate accuracy.
- Does not support 1-port measurements.
- Using true mode and measuring ADC inputs simultaneously may not result in accurate ADC measurements. In this case, adding two more ADC measurements to the display will result in accurate ADC measurements.

The following standard VNA features are **NOT** available with iTMSA measurements:

- **External Multiport Test Set Control** (Option S9x551A/B)
- **Time Domain Pulse measurements** in Wideband Pulse are NOT supported.
- **Segment Sweep**
- **Frequency Offset Measurements** (opt S9x080A/B)
- **mmWave Measurements** are allowed but with differential and S-Parameter measurements only. Absolute power measurements are not possible.

True Mode Stimulus Concepts

A balanced device is designed to receive input simultaneously across two ports. Standard VNA Balanced measurements apply stimulus to one port at a time, measures the responses, and calculates the theoretical balanced responses. Learn more about balanced measurements.

True Mode Stimulus uses two VNA sources to apply either truly differential (180 degree out-of-phase) or truly common (in-phase) signals across the input of a balanced device. VNA receivers measure the single-ended response at the output of the device and calculate the balanced response.

When operating in non-linear regions, a device may respond differently to single-ended stimulus than
to True Mode Stimulus. Thus, True Mode Stimulus capability allows you to understand when, and if, True Mode Stimulus is required.

For more detailed information on this measurement technique, see the following white papers (internet connection required):

- New Methods & Non-Linear Measurements for Active Differential Devices
- New Measurement Results and Models for Non-linear Differential Amplifier Characterization

**How iTMSA Works - Overview**

The following is an overview of how iTMSA gathers and displays True Mode Stimulus data:

1. **Initial sweep** is performed to gather the initial phase deviation between the two sources at the reference plane.

2. **Measurement** The phase deviation between the two sources is set to the required value and the response is measured. For a differential sweep, the phase deviation of the two sources is set to 180° at the reference plane. For a common sweep, the phase deviation is set to 0° at the reference plane.

A forward direction measurement requires 2 sweeps for differential and 2 sweeps for common. A reverse direction measurement requires the same. Therefore, a complete measurement in both directions requires 8 sweeps. The iTMSA traces are updated when all of the necessary data is gathered in each direction.

iTMSA computes the raw S parameters with the following matrix:

\[
\begin{bmatrix}
\frac{a_1}{d_1} & \frac{a_1}{d_2} & \frac{a_1}{c_1} & \frac{a_1}{c_2} \\
\frac{a_2}{d_1} & \frac{a_2}{d_2} & \frac{a_2}{c_1} & \frac{a_2}{c_2} \\
\frac{a_3}{d_1} & \frac{a_3}{d_2} & \frac{a_3}{c_1} & \frac{a_3}{c_2} \\
\frac{a_4}{d_1} & \frac{a_4}{d_2} & \frac{a_4}{c_1} & \frac{a_4}{c_2}
\end{bmatrix}
\begin{bmatrix}
a_1 \\
a_2 \\
a_3 \\
a_4
\end{bmatrix}^{-1} =
\begin{bmatrix}
S_{11} & S_{12} & S_{13} & S_{14} \\
S_{21} & S_{22} & S_{23} & S_{24} \\
S_{31} & S_{32} & S_{33} & S_{34} \\
S_{41} & S_{42} & S_{43} & S_{44}
\end{bmatrix}
\]

**Legend:**

- d1: differential stimulus in balanced port 1.
- d2: differential stimulus in balanced port 2
c1: common stimulus in balanced port 1.

c2: common stimulus in balanced port 2.

**Using iTMSA**

A Standard (default) S-Parameter channel is used for iTMSA measurements.

**How to create an iTMSA trace:**

1. Preset the VNA

2. Then do the following:

**Using Hardkey/SoftTab/Softkey**

1. Press **Meas > Balanced > Topology...**

**Balanced DUT Topology / Logical Port Mapping (with iTMSA Option S9x460A/B) dialog box**

Learn about iTMSA.

Topology
The following topologies are available in True Mode Stimulus.

- **BAL** DUT has a single balanced port.
- **BAL-BAL** DUT has two balanced ports.
- **BAL-SE** DUT has one balanced port and one single-ended port.
- **BAL-SE-SE** - DUT has one balanced port and two single-ended ports.
- **SE-BAL** DUT has one single-ended port and one balanced port.
- **SE-SE-BAL** - DUT has two single-ended ports and one balanced port.

- **All SE**  
  (Changes all entries to Single-ended)

- **All BAL**  
  (Changes all entries to Balanced)

- **All Unused** (Changes all entries to Unused) This is a convenience feature to help set up custom topologies, but it is not possible to have only Unused ports. If the **OK** button is clicked and all ports are listed as Unused, the topology will be set up to have 1 SE Port.
- **Custom**
  (Maps the physical VNA ports to a device of balanced and single-ended logical ports for multi-port systems with greater than 4 ports.)

A balanced port can be any one of four physical port combinations:

1 - 3
1 - 4
2 - 3
2 - 4

**Port Z**

Provide an enable for both Common and Differential Conversion and SE Port Z Conversion.

**Balanced Port**  Shows all ports defined on the balanced topology page.

**Default Z**  Shows the default impedances that will be applied if the port Z conversions are not enabled. The SE Default Z always equals the System Zo defined for the VNA. The Differential and Common Default Z will display values calculated from the single-ended port impedances.
**Converted Z** User may enter the real or imaginary component of the impedance.

**Warning Dialog** The dialog is displayed if "Conversion" is enabled and "Apply Fixtures" is currently disabled.

**Offset**

**Balanced Port** Set the phase or power offset for the balanced port.

**True Mode** Shows whether True Mode is On or Off.
**Power Offset**  Specify power offset. Range is +/- 20 dB. This is in addition to the power level that is specified using the [Power and Attenuators dialog](#). Offset Power is NOT reflected on the power dialog nor on the X-Axis during a power sweep. A power offset may only be applied to a True Mode port.

**Apply Power Offset as Fixture**

When unchecked, output calculations are performed and displayed as though there is no stimulus power offset.

When checked, output calculations are performed and displayed using the power offset that is applied to the DUT. Use this setting to compensate for a component or fixture that may present a magnitude loss before the DUT.

**Phase Offset**  Specify offset for the balanced INPUT port. This is in addition to the standard offsets, which are 180° offset for the differential stimulus sweeps, and 0° for the common stimulus sweeps. A phase offset may only be applied to a True Mode port.

**Apply Phase Offset as Fixture**

When unchecked, output calculations are performed and displayed as though there is only the standard offset. Although additional Phase Offset is applied to the stimulus, it is ignored in the calculations of balanced differential and common mode output signals.

When checked, output calculations are performed and displayed using the actual phase offset that is applied to the DUT. Use this setting to compensate for a component or fixture that may present a phase delay before the DUT.

**Sweep**
Available only when **Sweep type = CW**.

Available ONLY for balanced pairs.

The phase of the selected active source port is swept relative to the phase of the other source port in the balanced pair. The active source port uses the logical port number.

Phase Sweep is similar to phase offset, except that for each data point, the phase 'offset' is incremented.

For example, with the topology that is selected in the above image: (Bal-Bal) Logical port 1 = VNA ports 1 and 3. For a phase sweep with 7 data points, from 0° to 180°, the phase difference between port 1 and port 3 increments 30° with each data point:

<table>
<thead>
<tr>
<th>Data point</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delta phase</td>
<td>0°</td>
<td>30°</td>
<td>60°</td>
<td>90°</td>
<td>120°</td>
<td>150°</td>
<td>180°</td>
</tr>
</tbody>
</table>

**Enable Balanced Phase Sweep**  Check to enable phase sweep for the specified port. If enabled and the VNA sweep type is not CW, the following dialog is displayed to turn on CW Sweep Type.
Start / Stop Phase  Enter phase values in degrees. Each sweep will start and stop at these settings.

Offset as Fixture

In the following image, the VNA phase sweep is shown as a phase shifter that is "virtually" located EITHER before the reference receiver (top) OR after the reference receiver (bottom) - NOT BOTH. This image is useful as a model ONLY.

| NOT checked | The phase shift occurs at each data point and the reference receiver measurement sees the same phase shift as the DUT. The response is measured as though a true phase sweep is stimulating the differential input to the DUT. |
| Checked     | The phase shift occurs at each data point, but the reference receiver measurement does NOT see the shift. Use this setting to compensate for a component or fixture that...

5940
shift occurs at each data point, but the reference receiver measurement does NOT see the shift.

Use this setting to compensate for a component or fixture that may present a phase shift before or after the DUT.

**Note:** Beginning with firmware version A.14.00, the **Enable Differential Source Only Mode** feature has been removed.

**One use for Phase Sweep**

Do the following to find the best operating point:

1. Phase sweep port 3, from 0° to 180°. Note the peak of Sdd21. This finds the phase offset of the input differential port.

2. Set port 3 **fixed offset** to the phase that has the highest Sdd21.

3. Then, phase sweep port 4 (balanced port 2) to find the phase offset of the output differential port.

4. Then set the port 4 to fixed phase offset found.

This measures the best possible case Sdd21 for the DUT.

**Power and Attenuators Settings**

Set stimulus power levels using the standard VNA Power and Attenuators dialog.

To set power, press **Power > Main > Power and Attenuators**...
Power and Attenuation (with True Mode Stimulus) dialog box help

When a True Mode Stimulus is selected in the Balanced DUT Topology dialog, the balanced ports are shown on the top rows of the dialog. The individual VNA port settings are displayed but can not be changed directly.

**Port Powers Coupled** Check to couple all power settings for Balanced Port 1 and Balanced Port 2. Clear this box to make independent power settings for these logical ports.

**State** Should be left in Auto for iTMSA measurements. Learn more about this setting.

**Port Power** Set power for the balanced port. Power for VNA ports, shown below balanced ports, are set to 3 dB less, or half power. Power Offset is made in addition to this setting, and on only VNA port 3 and port 4. Offset Power is NOT reflected on this dialog nor on the X-Axis.

**Start and Stop Power** Available when sweep type is set to power sweep.

**Auto Range** Check to allow the VNA to select the optimum attenuation value to achieve the specified test port power. Clear to manually set the attenuation for each port. Type or select the attenuation value in the adjacent Attenuator Control box. When the attenuator setting of a logical port is changed, then the attenuators of the VNA ports associated with that logical port change to the same value.

**Leveling Mode** Open Loop leveling is available only on ports 1 and 3. Learn more.

**Note:** The range of leveled power (ALC range) for balanced ports is 3 dB higher than it is for each individual VNA port. For example, if a VNA source port with 0 dB attenuation will supply leveled power from -30dBm to +15dBm, then the balanced logical port has a range of -27dBm to +18dBm. Learn more about Leveled Power.

---

Calibration with iTMSA

**Note:** Uncalibrated True Mode Stimulus are NOT at all accurate.

Perform or recall a SMART Cal exactly like any other 3 or 4-port cal.

Press **Cal > Main > Other Cals > Smart Cal...**

- All Cals are performed as single-ended.
- Supports all Fixturing and Port Extension features.
- Supports Guided Power Cal.
- Supports Enhanced Response Cal and Source Power Cal.
Source Power Cal

Perform a Source Power Cal on:

- Port 3 for BAL Port 1
- Port 4 for BAL Port 2

Port 1 and Port 2 power levels are adjusted to these ports in the initial sweep.

Receiver Measurements

Any pair of receivers can be viewed as a ratio using the following dialog.

To select these measurements, press Meas > Receivers.

Create / Change Receiver Measurements (with True Mode Stimulus) dialog box help

Click Activate

- For RATIOED measurements, Select a receiver for the Numerator and select a receiver for the Denominator.
- For UNRATIOED measurements, Select a test port receiver (A, B, C, or D) for the Numerator. Reference receiver measurements are NOT accurate. Select 1 for the Denominator.

For example, with a Bal-Bal topology, the above selections show a R3/R1 measurement. R (reference) receivers measure the stimulus to the DUT. An R3/ R1 trace shows the difference between the two sources that comprise logical port 1. With Log format, a power offset between the two sources is visible. With Phase format, a phase offset is visible.

Source Port  Specifies whether a Differential stimulus or Common mode stimulus is used for the measurement.

- With Source Port 1 or 2 selected, then Differential stimulus is used for the unratioed measurement which causes 180° offset between the sources.
  - Source Port 1 = Differential stimulus on BAL1 port
  - Source Port 2 = Differential stimulus on BAL2 port
With Source Port 3 or 4 selected, then **Common** mode stimulus is used for the unratioed measurement which causes **0° offset** between the sources.

- Source Port 3 = Common-mode stimulus on BAL1 port
- Source Port 4 = Common-mode stimulus on BAL2 port

### Differential Input and Output Power Measurement

Equation Editor is used to calculate and display the Differential Input and Output power levels.

This procedure assumes a Bal-Bal topology which requires the following port assignments:

- Balanced Port 1 = VNA ports 1 and 3
- Balanced Port 2 = VNA ports 2 and 4

### Procedure

1. **Preset** the VNA
2. Perform a **4-port** Guided Power Calibration if desired.
3. Then press **Trace**, select **Trace Setup**, then select **Receivers**.
4. Complete the dialog as follows, then click OK.

<table>
<thead>
<tr>
<th>S-Parameter</th>
<th>Balanced</th>
<th>Receivers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. The above FIVE traces and the default (S11) trace should be visible on the VNA screen.
6. Click **Tr1** (S11). This is the 'dummy' trace that will become an equation trace.
7. Then press **Math > Analysis > Equation Editor**.

8. In the **Equation** field, enter `(Tr2-Tr4) / sqrt(2)`

9. Press **OK** to close Equation Editor. The **Tr1** trace is now showing Differential Output power.

10. For Differential Input power, activate **Tr3** (C receiver).

11. In Equation Editor, enter `(Tr5-Tr6) / sqrt(2)`. Press **OK**.

12. The **Tr3** trace is now showing Differential Output power.

*The traces used to calculate and display Differential Input and Output Power*
The S93070xB Modulation Distortion application characterizes the nonlinear distortion of RF microwave amplifiers and converters under a modulated signal.

  - Spectrum Analyzer Settings
• Unprecedented dynamic range through coherent averaging (repetitive waveforms are used)
• Corrects for port match and establishes calibration reference plane (VNA vector error correction is applied)
• No need to demodulate the response signal
• Accurate measurement of modulated signal with VNA receivers
• Analysis of nonlinear behavior of the device under modulated signal stimulus
• Measure input and output signals coherently
• Delivers figure of merits of the device commonly used in the industry (ACP, EVM, NPR)

Requirements

• Modulation Distortion Option S93070xB
• 2-Port or 4-Port PNA/PNA-X with option 22x or 42x

• Supported external sources:
  • E8267D PSG Vector Signal Generator
  • M8190A with E8267D PSG Vector Signal Generator
  • M9383A/B, M9384B (wideband vector, 44 GHz, with enhanced phase noise)

  **Note:** When setting up an M9383A, M9383B, or M9384B source in the External Device Configuration dialog, select `MXG_Vector` as the driver (they are code compatible).

  • N5182B MXG RF Vector Signal Generator
  • N5192A and N5194A UXG Vector Adapter

• Option S93083A/B provides Frequency Converter Application (FCA) for converter measurements (includes Scalar Mixer (SMC) and Vector Mixer (VMC) measurements).

• Option S9x084A/B provides the ability to measure frequency converters that have an embedded LO.

• Windows 7 or Windows 10 operating system
A Vector Signal Generator is used to generate a repetitive signal with a given CCDF (Complementary-Cumulative-Distribution-Function) and PSD (Power Spectral Density).

**Compact Modulated Waveform**

The modulation distortion application uses a short waveform period to perform an accurate measurement within a relatively short time frame. This process is known as compacting the waveform.

For example, use this process if you want to determine the response of the DUT using a waveform under a specific modulation scheme. The VNA firmware helps to create a slice of the parent waveform. The waveform inherits the frequency signature and statistical characteristics. The sliced waveform is called the compact test signal.

The parent waveform is created using the Keysight Signal Studio Software and is a .wfm file. (The parent waveform is also referred to as the original waveform.) In addition, you can use a .csv file format that has a timestamp, I, and Q that uses a comma to separate the values.
Note: Encrypted .wfm files created using the N5182B MXG RF Vector Signal Generator are not supported.

The following parent waveform is a 5G NR 100 MHz bandwidth signal:

The PNA-X firmware uses a unique algorithm to determine the most statistically representative slice from the parent signal. The results are from the parameters selected in the Create Modulation dialog. The firmware then applies a brick wall filter to remove spectral leakage when the compact test signal plays.

The following shows the CDF of a parent signal and subset slice:

Depending on the parameters selected in the Create Modulation dialog, the compact test signal
displays different characteristics, which can affect the measurement result.

For example, if you are using a 5G NR 100 MHz bandwidth waveform as a parent waveform to create a compact test signal, the plots below illustrate two different compact test signal characteristics when using different parameters for the same parent waveform.

The yellow trace indicates the parent waveform, and the blue trace shows the compact test signal. The plots on the left display a compact test signal consisting of 1,001 tones with a 100 kHz tone spacing. The plots on the right display a compact test signal consisting of 10,001 tones with a 10 kHz tone spacing.

The following plots represent the spectrum of the waveform. The results show what the waveform looks like in the frequency domain by applying the Fast Fourier Transform (FFT) to each waveform. The frequency signature of signals in both the left and right plots have the same bandwidth as the original signal. The original signal has a higher out-of-band spectrum. The compact test signal has a low out-of-band spectrum that uses the brick wall filter for cleaning the signal.

CTS #1: 1,001 Tones  
CTS #2: 10,001 Tones

The following plots represent the position of a compact test signal within the parent signal in the time domain. The numbers shown represent the waveform length (reciprocal of the tone spacing). The left compact test signal has a waveform length of 10 us; the waveform length of the right compact test signal is 100 us. A finer tone spacing waveform results in an extended period of the compact test signal waveform.

CTS #1: 1,001 Tones  
CTS #2: 10,001 Tones
The following plots represent the complementary cumulative distribution function (CCDF) curve of the parent signal, compact test signal, as well as Gaussian distribution (pink trace). The CCDF of this specific parent waveform is in alignment with the Gaussian distribution. The CCDF of a compact test signal that consists of 10,001 tones aligns with the parent waveform across the entire probability. The CCDF of a compact test signal that includes 1,001 tones aligns with the parent waveform, but only until it is approximately a 0.1% probability.

**Measuring Spectrum Using VNA Receivers**

The following is a simplified block diagram of a modulation distortion setup showing the VNA receivers and VSG.
The VSG replays the compact test signal without any interruptions. Three VNA receivers capture the spectrum at the reference plane at the input and output of the DUT. The instantaneous bandwidth of the VNA ADC (Analog-to-Digital Converter) is at 30 MHz. When the modulation distortion application measures the spectrum of the signal with a bandwidth wider than 30 MHz, it moves the local frequency of the VNA to measure the spectrum for each instantaneous bandwidth. It then combines the captured partial spectrum to obtain a complete spectrum response.

When the modulation distortion application measures the spectrum for each section, it uses multiple receivers coherently and applies linear calibration terms. The modulation distortion application offers a measuring technique where the VNA completes accurate vector corrected measurements at the reference plane.

The block diagram above shows how the VNA measures the input signal and the output signal spectrum:

- Signal generator generates a repetitive compact test signal.
- VNA receiver measures the input signal spectrum and output signal spectrum in the frequency domain.
- Output signal spectrum has spectral regrowth created by the nonlinear response of the DUT.
Spectrum Decomposition

The DUT is stimulated with a low-level signal to measure its linear parameters and a high-level modulated signal to measure its distortion characteristics. The modulation distortion application processes the data and compares the input spectrum $X(f)$ and the output spectrum $Y(f)$ using a process known as spectral correlation. As a result, the modulation distortion application decomposes the output signal spectrum into two parts: $H(f) \cdot X(f)$ and $D(f)$. $H(f) \cdot X(f)$ linearly correlates to the input while $D(f)$ represents the distortion which does not correlate to the input.

Computing ACPR and EVM

Computing ACPR is similar to the traditional signal generator and signal analyzer approach. The channel power of the in-band channel of interest and the channel power of the adjacent channel band is evaluated. The ratio between the BAND and AC is then computed.

For the EVM computation, the compact test signal plays continuously in the signal generator following the measurement of the input and output response of the DUT in the frequency domain. Spectrum correlation is then performed to compute the EVM.

When viewed in the frequency domain, this signal is a mult-tone "grid" of frequencies. The data is measured on this multi-tone grid.
Optimizing Modulation Distortion Measurements

Signal-to-noise ratio of the spectrum measurement

Poor EVM occurs when the random noise is the dominant factor of the EVM, where it likely happens at the left side of the bathtub curve. Improving the SNR of the measurement can improve the accuracy of the measurement.

Noise bandwidth

The resolution bandwidth and the number of coherent averaging of the measurement determine the noise bandwidth. The default value of the noise bandwidth is 1 kHz. Noise bandwidth determines the signal-to-noise ratio (SNR) of the measurement system and measurement time.

As noise bandwidth decreases, modulation distortion increases the underlying coherent average. The result is a wider signal noise ratio and longer measurement time. The resolution bandwidth is set automatically with firmware from the compact test signal waveform length; it is a discrete number. It is the closest value to the one you entered.

Signal noise ratio of the vector signal generator

The SNR of the VSG differs depending on multiple factors. A key factor is the number of tones of the compact test signal. As you increase the number of tones, the SNR of the VSG degrades. For example, compare a compact test signal with 1,000 tones and a compact test signal with 10,000 tones given the same channel power: -10dBm.

The tone power level of the compact test signal with 1,000 tones is -40 dBm, while the tone power of the compact test signal with 10,000 tones is -50 dBm. If the measurement has the same noise floor for each compact test signal, the compact test signal with 1,000 tones is 10 dB better than the compact test signal with 10,000 tones.

Nonlinearity of the test receiver
If there is a nonlinear response in the test receiver, it is unable to distinguish nonlinearity that comes either from the DUT or the receiver of the test system. The PNA-X test receiver needs to be in linear when measuring the signal. When it measures the subtle nonlinearity of a DUT, such as the EVM level of 1%, the recommendation is to keep the power level less than -5 dBm at the test port of the PNA-X. Use the receiver attenuator to adjust the power level if the test port power is higher than -5 dBm.

**Nonideal compact test signal**

The linear error due to the test system can be corrected to have the desired compact test signal at the reference plane. You can do this by adjusting the channel power and linear flatness response using the modulated correction feature. Also, out-of-band spectral regrowth is suppressible by adjusting the ACPR.

**Compact test signal statistical characteristics**

It is critical to understand that nonlinear characteristics of the DUT under modulated signal condition is highly dependent on the stimulus signal. It is also important to create the compact test signal that can stimulate the DUT with the most representative statistical characteristics to the practical usage of the DUT.

The best practice is to align the complementary cumulative distribution function (CCDF) of the compact test signal with the parent waveform. However, the CCDF is not the same since the compact test signal is a slice of the parent waveform. The recommendation is to match the CCDF until it is 0.1% of probability. By choosing more than 3,000 tones gives you a good match of the CCDF - up to 0.1%.

**Measurement throughput**

Faster measurement time gives faster throughput to complete the evaluation. You can determine measurement time using these parameters:

- signal analyzer span
- noise bandwidth
- compact test signal number of tones

Measurement time and measurement accuracy is generally a trade-off. It is essential to have the right balance of speed and accuracy to modify the parameter depending on the target measurement value.

**Modulation Distortion Graphical User Interface**
The GUI consists of setup dialogs accessed by clicking on their corresponding tabs. In this way, configurations can be set up quickly. See Configuring Distortion Measurements for information about these dialogs.
The Create... button in the Modulate tab accesses the Create Modulation dialog used to set up the compact test signal. See Creating Modulation Files for information about this dialog.
**Create Modulation**

**Modulation Type** Compact  
**Source Name** None

**Original Signal**
- **Filename**: VR_256QAM_120kHz_SCS_100MHz_122x88MHz5R.wfm
- **Sample Rate**: 122.880 MHz  
- **Signal Span**: 65.0768 MHz  
- **Number of Samples**: 1228800  
- **Carrier Offset**: -75.450 kHz  
- **Waveform Period**: 10.000 ms

**Compact Signal**
- **Signal Span**: 05.076800000 MHz
- **Waveform Period**: 10.51818 usec
- **Number of Tones**: 1001
- **Peak-to-Avg**: 11.487 dB
- **Carrier Offset**: -75.450 kHz
- **DAC Scaling**: 85.00 %

**Calculated Result**

The calculation is complete, ready to save.
Starting and Exiting Modulation Distortion

In this topic:

- Starting Modulation Distortion Application
- Exiting Modulation Distortion Application

Starting Modulation Distortion Application

How to start Modulation Distortion

**Using Hardkey/SoftTab/Softkey**

1. On the VNA, press `Meas > S-Param > Meas Class.....`
2. Select Modulation Distortion, then click OK.
3. In the Confirm Measurement Class Change dialog, click OK to proceed or Cancel to exit.
4. The Modulation Distortion application is displayed (shown below).

**Using a mouse**

1. Click Instrument.
2. Select Meas Class....
3. Select Modulation Distortion, then click OK.
4. In the Confirm Measurement Class Change dialog, click OK to proceed or Cancel to exit.
5. The Modulation Distortion application is displayed (shown below).
Exiting Modulation Distortion Application

1. Select a different Measurement Class for the currently active channel.
Configuring Distortion Measurements

The Modulation Distortion dialog settings are contained within four tabs: **Sweep**, **RF Path**, **Modulate**, and **Measure**. A fifth tab called **Mixer** contains settings for converter measurements (Option S93083A/B FCA required).

For convenience, the Spectrum Analyzer tabs can be displayed as follows:

1. Right-click in a Modulation Distortion dialog.
2. Select **Show Expert Tabs (on|OFF)**.
3. The tabs are displayed next to the Modulation Distortion tabs:

   ![Modulation Distortion Converter Setup](image)

4. To display the Spectrum Analyzer Advanced tabs, right-click again in a Modulation Distortion dialog then select **Show SA Advanced (on|OFF)**:
5. The Spectrum Analyzer Advanced tabs are displayed:

In this topic:

- Create a Modulation Distortion Channel
- Opening the Modulation Distortion Dialog
- Create a Modulation Distortion Converter Channel
- Opening the Modulation Distortion Mixer Setup Dialog

Create a Modulation Distortion Channel

1. On the VNA front panel, press Meas > S-Param > Meas Class...

2. Select Modulation Distortion, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.

3. The Modulation Distortion dialog is displayed.

Opening the Modulation Distortion Dialog

Accessing Modulation Distortion Settings

Using Hardkey / SoftTab / Softkey

1. Press Setup > Main > MOD Setup...

Using a mouse

1. Click Stimulus.

2. Select MOD Setup...
Create a Modulation Distortion Converter Channel

1. On the VNA front panel, press **Meas > S-Param > Meas Class...**

2. Select **Modulation Distortion Converters**, then either:
   - **OK** to delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

3. The **Modulation Distortion Mixer Setup** dialog is displayed.

**Sweep Tab in dialog help**

Fixed and Power Sweep Type Dialogs for Modulation Distortion Measurement Class (MOD)
Fixed and Power Sweep Type Dialogs for Modulation Distortion Converters Measurement Class (MODX)
Sweep Type

**Fixed** - Fixed sweep measures a modulated signal with a fixed carrier LO frequency and power level.

**Power** - Power sweep sweeps the total power of the modulated signal at multiple power levels defined by a start/stop power level. This power may be defined at the input or output of the
DUT, depending on the leveling defined in the RF Path tab. The current start/stop power settings are displayed next to the Power Sweep button.

**Carrier Frequency** - (Modulation Distortion only) Sets the carrier LO frequency.

**Carrier Freq In** - (Modulation Distortion Converters only) Sets the carrier frequency at the input of the mixer.

**SA Center/SA Start** - (Modulation Distortion only) Sets the Spectrum Analyzer display center or start frequency.

**SA Center In/SA Start In** - (Modulation Distortion Converters only) Displays the Spectrum Analyzer center or start frequency at the input of the mixer.

**SA Span/SA Stop** - (Modulation Distortion only) Sets the Spectrum Analyzer display span or stop frequency.

**Note:** The SA displayed frequency range is limited to the measurement band frequencies

**SA Span In** - (Modulation Distortion Converters only) Sets the Spectrum Analyzer span or stop frequency at the input of the mixer.

**SA Stop In** - (Modulation Distortion Converters only) Displays the Spectrum Analyzer span or stop frequency at the input of the mixer.

**Noise BW** - Noise BW is equal to the Resolution BW divided by the Vector Average factor. If a Power Sweep Type of List is selected and Custom Noise BW values are set, the word Swept is displayed in the **Noise BW** box. Learn more.

**Set Power At** - Sets power level used for the distortion test at either the input or output of the DUT.

**Buttons**

**Power Sweep...** button - Accesses the **Power Sweep** dialog.

**Power Sweep Type - Ramp**

**Ramp** - Selects a ramp type power sweep and displays the following information:
Start Power At - Sets the start power value for the power sweep.

Stop Power At - Sets the stop power value for the power sweep.

Number of Powers - Sets the number of power points to measure.

Noise BW - This is the same value as shown in the Sweep tab dialog.

Auto-Increase NBW at High Powers - The Noise BW setting will be used for the minimum power level. As the power level increases, the Noise BW will increase automatically. This results in faster measurements and ensures that the noise error is approximately the same for each power level.

Power Sweep Type - List

List - Selects a list of power values to define a power sweep and displays the following information:
Index - Each index entry defines a power level, source and receiver attenuation, and noise bandwidth for the power sweep.

Power - Sets the power level for the specific index number.

Src Atten -

- Fixed Atten - Setting one attenuation value in the column sets them all to the same value.

- Custom - Settings for each index may be different. Note that the Src Atten entry on the RF Path tab will indicate Swept under this condition.

Rcvr Atten -

- Fixed Atten - Setting one attenuation value in the column sets them all to the same value.

- Custom - Settings for each index may be different. Note that the Rcvr Atten entry on the RF Path tab will indicate Swept under this condition.

Noise BW - This is the same value as shown in the Sweep tab dialog if the Noise BW column is set to One NBW or Auto-Increase.

- Fixed NBW - Setting one noise bandwidth value in the column sets them all to the same value.

- Custom - Settings for each index may be different. Note that the Noise BW entry on the Sweep tab will indicate Swept under this condition and will be grayed-out.
Auto-Increase - The Noise BW setting will be used for the minimum power level. As the power level increases, the Noise BW will increase automatically. This results in faster measurements and ensures that the noise error is approximately the same for each power level.

Add Row button - Adds a row after the currently selected row in the table.

Delete Row button - Deletes the currently selected row.

Load... button - Loads a .csv file into the table.

Save... button - Saves the table to a .csv file.

DC Sources... button - Accesses the standard dialog for controlling power supplies. Learn more.

Sweep Details... button - Accesses the following dialog:

**Dialog for Modulation Distortion Measurement Class (MOD)**

![Sweep Details dialog](image)

**Dialog for Modulation Distortion Converters Measurement Class (MODX)**
Force RF Power OFF at the End of Sweep - System Preference - If enabled, RF power is turned off at the end of a sweep.

Note: This setting is a system-wide preference; the state of this setting will affect all measurement channels and the state will not change if the VNA is preset or restarted.

Delay Before Start of Sweep - Same as Sweep Delay in a standard channel.

Delay Before Distortion Measurement - Adds delay after the linear S-parameter sweep and before the distortion measurement to allow the RF source to settle.

Linear S-Parameter Measurement Sweep (Modulation Distortion only)

Enable S-Param Sweep - Enables S-parameters to be measured at the low linear power level. If disabled (default), curve fitting (smoothing) is used instead of the S-parameter sweep. Curve fitting can be adjusted by varying the window aperture using the Distortion Measurement Correlation Aperture setting in the Measurement Details dialog.

Note: When disabled, some measurements, such as S-parameters, will display -200 dB because they will not be measured.

S-Param Source - Selects source and signal used to measure S-parameters.
**External Vector - Chirp** - Selects a chirp signal from the external signal generator for measuring S-parameters.

**S-Param Power** - Sets the power level used at the DUT input to measure the DUT gain when operating in its linear region. The linear gain is used to calculate distortion.

**S-Param Freq Step** - Frequency step size setting used when measuring S-parameters.

**S-Param IFBW** - Bandwidth setting when measuring S-parameters.

**Re-use Previous S-Parameter Measurements If Available** - If disabled, S-parameters will be measured at the low linear power level. If enabled and compatible measurements exist from a previous sweep, those measurements will be used and a Linear S-parameter sweep will not be performed. If enabled and compatible measurements are not available, then a Linear S-parameter sweep will be performed.

**Apply** button - Applies any changes to the settings in this dialog.
Dialog for Modulation Distortion Converters Measurement Class (MODX)

Set Power At DUT In - Displays the DUT power set in the Sweep tab.

VNA Source Attenuator - Sets the VNA's internal source attenuator (PXI/USB VNA does not support this)

- **Include** - When selected (default), the external modulated source passes through the attenuator of the specified PNA source and the attenuator setting is used to calculate the power levels. If a Power Sweep Type of List is selected and Custom Src Atten values are set, the word Swept is displayed in the VNA Source Attenuator box.

Nominal Source Amp - Sets the nominal gain (positive number) from an amplifier or loss (negative number) due to an attenuation, cable loss, etc. This value is used by the Set Power At function, receiver leveling, and calibration. This value is equal to the Power Offset setting found on the Offsets and Limits dialog.

DUT Input - Sets the VNA port number that is connected to the DUT input.

Nominal DUT Gain - Sets the nominal DUT gain. This value is used by Set Power At DUT Out, receiver leveling, and calibration. This function is also displayed on the calibration dialog.
**DUT Output** - Sets the VNA port number that is connected to the DUT output.

**Receiver Attenuator** - Sets the VNA's internal receiver attenuator for the currently selected output port.

**Buttons**

**RF Path Config...** button - Accesses the RF Path Configuration dialog.

**Offsets and Limits...** button - Accesses the Offsets and Limits dialog.

**Apply** button - Applies any changes to the settings in this dialog.

**Mixer Tab in dialog help**

**Converter Stages** - Selects between 1- or 2-stage mixer configuration.

**Enable Embedded LO** - Check to enable measurements of mixers that have a fixed LO inside the DUT.

**Note:** Embedded LO does not support signals with a tone spacing of less than 1 kHz.

**Setup...** - Opens the Embedded LO dialog.
Enable Embedded LO - Check to enable measurements of mixers that have a fixed LO inside the DUT.

Tuning Method - These settings determine the amount of time spent versus the degree of accuracy to which the LO Frequency is measured. Accuracy is compromised when noise starts to appear on the measurement trace.

- **Broadband and Precise** Does the entire tuning process for each background sweep.

- **Precise Only** Does NOT perform broadband tuning on each sweep. Use this setting when the embedded LO is stable. The signal (after broadband) must be within ½ the tuning IFBW. If the signal will always be within ½ the IFBW, broadband tuning is not needed. Most satellite components are within 3 kHz absolute so might not need broadband tuning.

- **Disable Tuning** Only the previously measured LO Frequency Delta is applied
to the reference mixer LO and VNA receivers.

**Tune every** - Set the interval at which tuning is performed before a measurement sweep. 'Tune every 3 sweeps' means that every third measurement sweep is preceded by tuning sweeps. If the embedded LO drifts, or if regularly changing DUTs, use 'Tune every 1 sweep'.

**Broadband Search** - Set the frequency span over which to measure the embedded LO frequency.

**Noise BW** - Noise Bandwidth used for Broadband and Precise tuning sweeps. This sets the resolution in the Broadband sweeps.

**Max Iterations** - The maximum number of Precise sweeps to make. When this number is reached, the final measurement is used.

**Tolerance** - When two consecutive Precise measurements are made within this value, the final measurement is used. If this is not achieved within the Max Iterations value, then the last measurement is used. This is the best of the 'Tunings settings' to change to improve accuracy.

**LO Frequency Delta** - The absolute difference between the measured embedded LO frequency and the LO setting that is entered in the Mixer Tab dialog.

**Find Now** - The VNA finds and measures the actual LO frequency using the current dialog settings. This data is displayed in the **Status** box.

**Default** - Resets the LO Frequency Delta and Tuning parameters to their default settings.

**Input** - Input frequency defined on the Sweep tab.

**IF** - Intermediate frequency between stage 1 and stage 2 for a 2-stage mixer configuration calculated from the mixer equation selection.

Choose from the following mixer equations:

- IF=Input+LO1
- IF=Input-LO1
- IF=LO1-Input

**Output** - Mixer output frequency calculated from the mixer equation selection.

Choose from the following mixer equations for a 1-stage mixer configuration:
Choose from the following mixer equations for a 2-stage mixer configuration:

- Output=IF+LO2
- Output=IF-LO2
- Output=LO2-IF

X - The combination of numerator / denominator forms a fractional value that is multiplied by the input and LO frequency ranges. Learn more.

**LO/LO1/LO2** - Sets the LO frequency.

**Source Name** - Select Not Controlled to allow an external source to provide a Fixed LO Frequency at all times. Otherwise, select an internal VNA source or External source to be used as the LO. Learn how to Configure an External Device (Source).

**Power** - Sets the LO power.

**Leveling**

- **Open Loop** - No ALC or receiver leveling. No leveling is used in setting the power.
- **Internal** - ALC leveling. Power level within an attenuator setting is limited to the ALC range.

**Attenuator** - Selects the receiver attenuation.

**Save... button** - Saves the mixer configuration to a .mrx or .mxrx file.

**Load... button** - Loads an existing mixer configuration file.

**Apply** button - Applies any changes to the settings in this dialog.
**Dialog for Modulation Distortion Measurement Class (MOD)**

Source - Selects sources that have been defined in the External Device Configuration dialog or selects Source3 (requires Option S93072B, Option XSB, Option S93070xB or Sx090A/B, and either Option 422 or Option 423).

**Dialog for Modulation Distortion Converters Measurement Class (MODX)**
Add Source... - Adds a new external source using the External Device Configuration dialog.

Source3 - With Option S93072B Arbitrary Waveform Generation on XSB Port (requires Option S93072B, Option XSB, Option S93070xB or Sx090A/B, and either Option 422 or Option 423), an internal third RF source can be selected from the SRC3 connector on the rear panel. Refer to Set Up Source3 Modulation Source - Option S93072B for important setup information.

**Note:** If the source selection is changed, and if a modulation file is selected and Enable Modulation is checked, then the modulation file will be automatically loaded into the source.

Modulation File - Displays the currently loaded modulation file. Supported file types include *.mdx, *.csv, and *.wfm. After selecting a modulation file, the following dialog is displayed to allow you to Autofill the measurement bands:

![Modulation Properties](image)

**Note:** Once a source is selected and a file is selected, the file will be automatically loaded into the source and the Enable Modulation box is checked.

Enable Modulation - Check to enable modulation.

Enable Source Correction - Check to enable source correction after a source modulation calibration is performed.

Enable LO Feedthru Monitor - Check to enable LO Feedthru monitor.

Enable Pulse - Check to enable standard pulse modulation.

Buttons

Load File... button - Loads an existing modulation file. Supported file types include *.mdx, *.csv, and *.wfm.

Create... button - Set up a modulation file. See Create Modulation dialog description.
Edit... button - Edit the currently loaded modulation file. See Create Modulation dialog description.

Properties... button

**Waveform Tab**

Displays the properties of the currently active modulation file, which was selected in the Modulation settings dialog. This information cannot be edited.

**Calibration Tab**

The Calibration tab displays the calibration files and their properties stored in the .mdx file. Each calibration displayed in the list is for one power level. Calibrations may have been performed on multiple power levels during a single calibration. In this case, multiple calibrations will be saved in the .mdx file. Any of these calibrations can be deleted by selecting the calibration name then clicking on the **Delete Cal** button.

Source Cal... button - Accesses the Modulation Cal - Setup dialog for performing source modulation calibration.

LO Monitor... button - See **LO Feedthru Monitor** dialog help below.

Pulse Setup... button - Opens the Pulse Setup dialog to set up a pulse measurement.
When the **OK** button is clicked, the following warning is displayed if a source has not been added or the Modulation file name has not been specified:

![Warning dialog]

Click **Exit with Errors** to exit the setup dialogs with the errors or click **Go Back** to return to the setup dialogs to fix the error.

**Apply** button - Applies any changes to the settings in this dialog.

---

**LO Feedthru Monitor** dialog help

The SA multitone NPR and the Modulation Distortion measurement use a vector signal source. It may have LO feedthrough leakage and the level may drift after calibration due to hardware imperfection. The LO feedthru calibration, as a part of source modulation calibration, reduces the LO feedthru by adjusting I/Q offset voltage. The LO Feedthru Monitor feature notifies you when you should take the calibration again.

You need to setup them depends on your measurement requirements.

- Monitoring receiver: It’ll be a reference receiver in most cases.
- Tolerance: Relative to Band Power (in dBc), Relative to Average Tone Power (in dBc) or Absolute level (dBm).

The firmware checks the LO feedthru level on every measurement. Exceeding the tolerance make a warning message of "LO Feedthru is out of tolerance on channel <n>. Perform Source Modulation Cal > LO Feedthru Calibration".

Supported measurements are Modulation Distortion measurements (MOD, MODX) and SA multitone NPR measurement. Non-multitone SA is not supported.
Enable LO Feedthru Monitor - Check to enable LO Feedthru Monitor. LO feedthru level is checked on every measurement.

Threshold Type -

- Relative to Band Power (in dBc): Compare with the band power.
- Relative to Average Tone Power (in dBc): Compare with the average tone power.
- Absolute level (dBm) - Check the LO feedthru absolute power level.

Threshold Level - Set the threshold level.

Measure LO at - Select the port to monitor the LO feedthru signal. Select the reference receiver in most cases.
Measurement Type - Selects the measurement type:

   **ACP** - Performs ACP measurement.

   **ACP+EVM** - Performs both ACP and EVM measurements.

   **Band Power** - Measures total power within a specified frequency span.

   **EVM** - Performs EVM measurement.

   **NPR** - Performs NPR measurement.

   **Multi-Band** - Displays the full Measurement Band Table.
Edit Table

Append Band - Adds a new band after the row with a currently selected active cell. Each band is assigned to a measurement type. Distortion parameters are calculated over the measurement bands.

Delete Band - Deletes the row with a currently selected active cell.

Edit Band Name - Change the Band Name.

Autofill Current Table from Mod File - Automatically sets up appropriate bands from the currently active modulation file loaded in the source.

Create New Table from Mod File - Automatically deletes the current table, then sets up appropriate bands for making measurements with information from the currently active modulation file loaded in the source.

Band Name - Right-click in the Band Name field to display a keyboard for editing the name.
**Carrier Offset Freq** - Offsets the Carrier integration bandwidth relative to the Carrier LO used to generate the modulation signal. Use the up/down arrows or double-click in the field to display the keypad for entering frequency.

**Carrier Integ BW** - Sets the Carrier integration bandwidth for the distortion measurement. The IBW is used to determine total signal power within a specified frequency span. For example, to calculate the total power of a signal composed of 100 tones spaced 1 MHz apart over a 100 MHz span, the signal power would be integrated over an IBW of 100 MHz.

**Notch Offset Freq** - (NPR measurement only) Sets the notch center relative to the carrier LO used to generate the modulation signal. Use the up/down arrows or double-click in the field to display the keypad for entering frequency.

**Notch Integ BW** - (NPR measurements only) Sets the integration bandwidth of the NPR notch measurement. The IBW is used to determine total signal power within a specified frequency span. For example, to calculate the total power of a notch composed of 100 tones spaced 1 MHz apart over a 100 MHz span, the notch power would be integrated over an IBW of 100 MHz.

**ACPLo Offset Freq** - (ACP measurements only) Offsets the lower ACP integration bandwidth relative to the LO used to generate the modulated signal. Use the up/down arrows or double-click in the field to display the keypad for entering frequency.

**ACPLo Integ BW** - (ACP measurements only) Sets the integration bandwidth of the lower ACP measurement. The IBW is used to determine total signal power within a specified frequency span. For example, to calculate the total power of a signal composed of 100 tones spaced 1 MHz apart over a 100 MHz span, the signal power would be integrated over an IBW of 100 MHz.

**ACPUp Offset Freq** - (ACP measurements only) Offsets the upper ACP integration bandwidth relative to the LO used to generate the modulated signal. Use the up/down arrows or double-click in the field to display the keypad for entering frequency.
**ACPUp Integ BW** - (ACP measurements only) Sets the integration bandwidth of the upper ACP measurement. The IBW is used to determine total signal power within a specified frequency span. For example, to calculate the total power of a signal composed of 100 tones spaced 1 MHz apart over a 100 MHz span, the signal power would be integrated over an IBW of 100 MHz.

**Buttons**

**Autofill** - Automatically fills in the measurement settings for all bands from the currently active modulation file loaded in the source:

<table>
<thead>
<tr>
<th>Modulation File Band(s)</th>
<th>Currently Defined Measurement Band(s)</th>
<th>Autofill Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single-band</td>
<td>Single-band</td>
<td>Use single-band Modulation File</td>
</tr>
<tr>
<td>Single-band</td>
<td>Multi-band</td>
<td>All bands set using single-band Modulation File</td>
</tr>
<tr>
<td>Multi-band</td>
<td>Multi-band but with fewer or same number of bands than Modulation File</td>
<td>First band set using first Modulation File band</td>
</tr>
<tr>

</tbody>
</table>

**Measurement Details...** button - Accesses the Measurement Details dialog.
**Distortion Measurement Correlation Aperture** - Sets the frequency span window used for modeling the DUT's gain and distortion.

- **Auto** - Check to automatically set **Distortion Measurement Correlation Aperture** to window size.

**ADC Anti-alias Filter** - Selects between auto and wide IF filter anti-aliasing path.

- **Auto** - Check to automatically set the ADC Filter setting based on the ADC Sampling Frequency. If the currently selected modulation waveform was created with Nyquist Rejection = OFF, then the VNA will measure the signal using the Narrow anti-alias filter in the receiver.

- **Wide** - Selects the ADC 38 MHz IF filter path.

- **Narrow** - Selects the ADC 11 MHz IF filter path. A warning message will appear if the Narrow IF filter path is selected and the Resolution Bandwidth is > 1 MHz.

**Modulation Filter** - (EVM and ACP measurements only) Sets the measurement filter to either **None** (default) or **RRC** (root-raised-cosine filter).

- **Alpha** - Sets Alpha factor of the filter.

- **Symbol Rate** - Sets the Symbol Rate of the filter. If **Auto** is selected, the symbol rate from the file is used. If no Symbol Rate is indicated in the file, then the Symbol Rate will be approximated from the bandwidth of the signal.

**EVM Normalization** - Identifies the scaling factor applied to the EVM measurements. Enter
Nominal DUT NF - Sets the DUT noise figure. This value is used by the EVM measurement. This setting adds noise to the measurement for more realistic results. The default is 0 dB. Setting the noise figure to a low value (-200 dB) will make EVM measurements without the effects of noise.

The following is the formula for computing EVM for a given NF value:

$$DEVM = \frac{k T^{1/2}}{F^{1/2}} \int_{f_0}^{f_1} X(f) \sqrt{f_0 - f_1} df$$

where:

- $DEVM$ : Measured Distortion EVM
- $k$ : Boltzmann constant
- $T$ : 290k
- $F$ : Noise Factor of DUT ($F = 10^{(NF/10)}$)
- $X(f)$ : input spectrum
- $f_0 , f_1$ : given frequency band to be computed

Apply button - Applies any changes to the settings in this dialog.
Accessing X-axis Type Settings

Using Hardkey / SoftTab / Softkey

1. Set up a Modulation Distortion Fixed or Power sweep measurement (see above).

2. Press **Trace** > **Trace 1-7** > **New Traces**.

3. Click on the **Distortion** tab then select a measurement parameter.

4. Press **Sweep** > **Main** > **X-axis Type**.

Using a mouse

1. Set up a Modulation Distortion Fixed or Power sweep measurement (see above).

2. Click **Instrument**.

3. Select **Trace**.

4. Select **New Traces**.

5. Click on the **Distortion** tab then select a measurement parameter.

6. Click **Stimulus**.

7. Select **Sweep**.

8. Select **X-axis Type**.

---

**X-axis Type dialog help**

The X-axis Type dialog is used to set the displayed x-axis annotation for a selected trace in Modulation Distortion or Modulation Distortion Converter measurements.

**Dialog for Modulation Distortion Measurement Class (MOD)**
Dialog for Modulation Distortion Converters Measurement Class (MODX)
Select

**Trace N** - Selects active trace.

**All Traces** - Selects all available traces.

**Sweep Type** - Based on the currently active sweep type for the selected channel.
**Fixed** - Fixed sweep measures a modulated signal with a fixed carrier LO frequency and power level. The Sweep Type selection determines the available X-axis Type. This selection can only be changed from the Sweep dialog.

**Power** - Power sweep sweeps the total power of the modulated signal.

**X-axis Type**

The X-axis Type setting defines the x-axis annotation for the displayed spectrum analyzer data. For Modulation Distortion Converter measurements, the x-axis annotation may be set to one of two frequency ranges: mixer input range and mixer output range.

For example, if a mixer has an input frequency of 1 GHz and an output frequency of 10 GHz, the X-axis Type is set to SA Freq In, and Pln and POut are measured, Pln and POut will both indicate they are measured at 1 GHz, even though POut is actually at 10 GHz. If the X-axis Type is set to SA Freq Out, Pln and POut will both indicate they are measured at 10 GHz, even though Pln is actually at 1 GHz.

For Modulation Distortion Channels (MOD)

**SA Frequency** - SA display showing the SA frequency settings.

**Power In** - Displays input power sweep.

**Power Out** - Displays output power sweep.

**Measured CarrIn1** - Measured input band power.

**Measured CarrOut2** - Measured output band power.

For Modulation Distortion Converters Channels (MODX)

**SA Freq In** - SA display showing mixer input range.

**SA Freq Out** - SA display showing mixer output range.

**Power In** - Displays input power sweep.

**Power Out** - Displays output power sweep.

**Measured CarrIn1** - Measured input band power.

**Measured CarrOut2** - Measured output band power.
### Fixed Parameters (Power Sweep Type only)

**Value** - Displays the spectrum analyzer frequency set in the Sweep dialog for a power sweep.

**Parameter** - (Modulation Distortion Converters Channels only) Selects either **SA Freq In** to display mixer input range or **SA Freq Out** to display mixer output range.
Creating Modulation Files

The **Create Modulation** dialog is used to create modulation files which can then be loaded into the source. The types of modulation files that can be created include **NPR Notch**, **Flat Tones**, and a shortened version of a modulation file called **Compact**.

### Original (Parent) Waveform

**Keysight Signal Studio Waveform (.wfm)**

Use a .wfm file, which is created using the Keysight Signal Studio Software.

In order to use a compact file (.mdx) which is created from .wfm, the corresponding license is required on the Signal Generator to play the .mdx.

When the waveform pack license is used, the original waveform file must be assigned / locked to the signal generator in order to use the .mdx created from the original waveform file.

**Note:** Encrypted .wfm files created using the N5182B MXG RF Vector Signal Generator are not supported.

**IQ file (.csv)**

Use a .csv file format that has a timestamp, I, and Q that uses a comma to separate the values.

No license is required on the signal generator to play the .mdx created from the .csv.

**Modulation Type** - Selects the modulation type (note that these define signals, not measurements):

- **Compact** - Compact signals cut a slice of the IQ data from an original waveform.
- **Flat Tones** - This signal is a set of constant amplitude tones over a defined signal span.
- **NPR Notch** - This signal is a set of constant amplitude tones over a defined signal span where a subset of those tones are set to zero over a notch span.
Compact Modulation Type

Compact signals cut a slice of the IQ data from an original waveform. The slice of IQ data is chosen that best fits in terms of statistical distribution (CCDF), then conditions the waveform so that it has the same spectrum signature as the original signal.

Original signal:

Compact signal:
Source Name - Selects the modulation source. Learn more.

Sample Rate - Sets the source sample rate.

  Auto - Automatically selects a sample rate for the active source depending on the modulation requested. If the modulation is invalid (for example, 0 Hz span), then Auto will default the sample rate to 100 MHz.

Filename - Select the filename of the original (parent) modulation file to be compacted.

  Sample Rate - Displays the sample rate of the original modulation file.

  Number of Samples - Displays the number of samples in the original modulation file.

  Tone Spacing - Displays the tone spacing of the original modulation file.

  Waveform Period - Displays the waveform period of the original modulation file.

  Signal Span - Displays the signal span value of the original modulation file.

  Carrier Offset - Displays the carrier offset value of the original modulation file.

Signal Span - Sets the frequency span of the modulated carrier.

Tone Spacing/Waveform Period - Sets the distance between each tone.

Number of Tones - Sets the desired number of tones. This setting is related to the span and tone spacing: (Number of Tones) = (Signal Span)/(Tone Spacing) +1.

Peak-to-Avg - Displays the peak-to-average value of the modulated signal.

Carrier Offset - Sets the carrier offset value relative to the carrier LO frequency.

Nmbr of Subcarriers - Allows selection of multiple carriers when defining a multicarrier signal. Select None, 2, 3, 4, 5, 6, 7, 8, or 9 from the pull-down menu. The default is None.
**Sub1 Span** - Sets the span of the subcarrier selected from the pull-down menu.

**Sub1 Offset** - Sets the offset of the subcarrier selected from the pull-down menu.

**DAC Scaling** - Sets the scaling factor used for the waveform (full scale = 100%). This ensures that the DAC filter does not output a signal that is larger than the DAC’s maximum output level, which can cause distortion in the system. Setting the scaling factor to 100% will usually cause excessive distortion.

**Signal Start Time** - Sets where to start the compact signal within the original signal. The compact signal is a slice of the original signal.

**Note:** The Priority checkbox must be checked to use this value.

**Number of Files** - Sets the number of modulation files to create. This function is useful to create several signals, compare them, then save the best signal.

**Priority** - Check to attempt to calculate values closer to the desired values.

**Calculated** - Displays the settings that were used to create the modulated signal.

**Enable Optimizer** - When enabled, the calculated modulated signal will be optimized according to the constraints defined in this group box.

If **Enable Optimizer** is disabled:

- Always creates a signal that can be measured by the PNA.

- If the Priority box for **Waveform Period** or **Tone Spacing** is checked, then this will attempt to create the exact desired period if possible.

- If the Priority box for **Number of Tones** is checked, then this will attempt to create the exact desired number of tones if possible.

- In some cases, the resulting file will be too large, or the frequencies will be inconsistent with the ADC frequencies. In these cases, the desired values will not be used.

**Setup...** button - Accesses the **Optimizer Setup** dialog.
Reject up to Harmonic Number - Set the number of test signal harmonics you want to be protected against. This adds constraints to the list of LOs used to cover the span.

Reject Nyquist Frequencies - Ensure that Nyquist images of the signal tones in the IF bandwidth are not falling back on top of real signal frequencies.

Enable Brick-wall Filter For Spectral Leakage - (Compact signals only) The brick-wall filter is applied to the band-power span calculated for the signal. The brick-wall filter cuts off signals outside this span. Uncheck this box to retain signals outside the calculated band power span.

Optimize Signal pull-down menu:

Frequency Tolerance - Set the allowed tolerance for tone spacing when calculating the modulation signal. Wider tolerance results in selection of tone spacing which require smaller files and less measurement time. If the tolerance to too small to provide a solution, then a solution is calculated with the minimum possible tolerance and the tolerance value will be changed.

Min Waveform Period - Minimizes the period of the waveform greater than or equal to the value (seconds).

Min Number of Tones - Minimizes the number of tones greater than or equal to the value. This will ignore the Number of Tones selection.

Max Tone Spacing - Maximizes the tone spacing less than or equal to the value (Hz). This will ignore the Tone Spacing selection.

Display - Select from the following:

Spectrum-Ideal - Displays the spectrum represented by floating point numbers, which results in a very low noise floor.

Spectrum-16bit - Displays the spectrum represented by 16-bit numbers, which results in more distortion.
**Time** - Displays the signal in the time domain.

**CCDF** - Displays the complementary cumulative distribution function.

**CCDF Error** - (Compact Modulation Type only) Displays the difference between the parent signal and created signal. The Y-axis is displayed in linear %.

**File** - Allows you to switch between multiple created signals for comparison, then save the best signal. Use **Number of Files** to specify the number of files to create for comparison.

**Number of Samples** - Displays the calculated file size. If there are no calculated results, **None** is displayed.

**Calculated Sample Rate** - Displays the calculated sample rate. If there are no calculated results, **None** is displayed.

**Measurement Time** - Displays the minimum measurement time for the calculated signal. If there are no calculated results, **None** is displayed.

**Filename** - Displays the name of the modulation file. If the calculated result has not been saved, **None** is displayed.

**Display Data Features**

Click-and-drag over a part of the display to zoom in on data.

![Graph with zoom feature](image-url)
Right-click in the display area to access the following menu:

- **Autoscale** - Automatically scales the data to fit vertically within the display grid area.

- **Display marker annotation** - Select to display marker annotation in the top-right of the display.

- **Show graticule** - Select to display graticules.

- **Add marker to:** - Select to add a marker to the displayed data trace. When a selection is made, the mouse pointer changes to a "+". Click in the display area and the marker will appear. Drag the marker to the desired position. Each time this selection is made, a new marker will be added to the data.

  Choose from:

  - **Original/Compact** - Add marker to the original data and/or the calculated compact
data when the Modulation Type selection is **Compact**.

**Flat Tones** - Add marker to flat tone data when the Modulation Type selection is **Flat Tones**.

**NPR Notch** - Add marker to notch data when the Modulation Type selection is **NPR Notch**.

**Copy to Clipboard** - Copies a bitmap of the trace control (Display) to the clipboard. It can then be pasted into any document that accepts bitmaps.

![Graph](image)

**Print...** - Prints the displayed data.

**Scale properties...** - Accesses the following dialog:
**Stimulus** - Sets the **Begin** and **End** frequency displayed on the X-axis.

**Response** - Sets the Reference level in the center of the Y-axis and sets the scale per division.

### Flat Tones Modulation Type

**Source Name** - See above.

**Sample Rate** - See above.

**Signal Span** - See above.

**Tone Spacing/Waveform Period** - See above.

**Number of Tones** - Select between odd or even number of tones and sets the desired number of tones. This setting is related to the span and tone spacing: \((\text{Number of Tones}) = \frac{\text{Signal Span}}{\text{Tone Spacing}} + 1\).

**Nmbr Tones, Odd** - This forces the optimizer to choose an odd number of tones. The optimizer will also choose an offset such that the carrier lands on one of the tones.
Nmbr Tones, Even - This forces the optimizer to choose an even number of tones. The optimizer will also choose an offset such that the carrier either lands on one of the tones, or exactly halfway between the tones.

Peak-to-Avg - See above.

Carrier Offset - See above.

Phase Type - Select Random, Fixed, or Parabolic.

Random Phase Seed - Sets the phase seed when Random phase is the Phase Type.

DAC Scaling - See above.

Priority - See above.

Calculated - See above.

Enable Optimizer - See above.

Optimize Signal pull-down menu - See above.

Display - See above.

NPR Notch Modulation Type
Source Name - See above.
Sample Rate - See above.
Signal Span - See above.
Tone Spacing/Waveform Period - See above.
Number of Tones - See above.
Peak-to-Avg - See above.
Carrier Offset - See above.
Phase Type - See above.
Random Phase Seed - See above.
Nmbr of Notches - Sets the number of notches in the modulated signal.

Notch Location - Select from the following:

  Symmetric - Locates the notch in the center of the signal span.

  Avoid Carrier - Locates the notch near the center of the signal span but will be shifted to
avoid the LO carrier feedthrough.

**Custom** - Allows the user to define the offset of the notch.

**Notch N Span** - Sets the span of the selected notch. The notch can be up to 10% of the **Signal Span**.

**Notch N Offset** - The offset frequency is the center frequency of the selected notch relative to the LO carrier frequency. Typically, the notch will have a 0 Hz offset, meaning it is centered on the LO carrier. If you have more than one notch, you can offset some of the notches from the carrier. For example, if you have three notches 1 MHz wide, you might set their offsets to -10 MHz, 0 MHz and +10 MHz so that they are spaced across the wideband carrier.

**DAC Scaling** - See above.

**Priority** - See above.

**Calculated** - See above.

**Enable Optimizer** - See above.

**Optimize Signal** pull-down menu - See above.

**Display** - See above.

**Buttons**

**Calculate** button- Calculates the result from the current settings. If calculated results exist then data is plotted on the display. If there are no calculated results then there is no plotted data and **No Data** is displayed. The calculated result is erased if you click on the **Defaults** button or **Recall...** button and recall a previously saved file.

**Save...** button - Saves the current modulation settings.

**Recall...** button - Recalls a previously saved modulation file.

**Edit...** button - Accesses the Edit Multitone dialog:
**Tone** - Tone number from 1 to N. Cannot be edited.

**Frequency** - Frequency of tone in Hz relative to the carrier. Cannot be edited.

**Power (dBm)** - Tone power in dBm. Click in the cell to edit.

**Phase (deg)** - Tone phase in degrees. Click in the cell to edit.

**State** - Click in the cell to turn the tone on or off.

**Set All Tones** - Set all tone states to on or off.

**Display** - Select which tones to display in the table (All Tones, On-Tones, or Off-Tones).

**Go To Row** - Jumps to the specified row. Enter the row number then press Enter.

**Save...** button - Saves the current multitone settings as a .csv file.

**Load...** button - Loads a previously saved multitone .csv file.

**Defaults** button - Restores default modulation settings for the current Modulation Type.
Distortion Measurement Parameters

In this topic:

- Spectrum Decomposition
- Distortion Model
- Accessing the Distortion Measurement Parameters
- Main and Distortion Tab Measurement Parameters
- Distortion Table

Spectrum Decomposition

The DUT is stimulated with a low-level signal to measure its linear parameters and a high-level modulated signal to measure its distortion characteristics. The modulation distortion application processes the data and compares the input spectrum \( X(f) \) and the output spectrum \( Y(f) \) using a process known as spectral correlation. As a result, the modulation distortion application decomposes the output signal spectrum into two parts: \( H(f)X(f) \) and \( D(f) \). \( H(f)X(f) \) linearly correlates to the input while \( D(f) \) represents the distortion which does not correlate to the input.

![Spectrum Decomposition Diagram](image)

Distortion Model

The following Distortion Model describes noise and distortion in an amplifier and will help in understanding the Distortion Measurement Parameters (shown below):

![Distortion Model Diagram](image)
Y(f) = C(f) * S21(f) * X(f) + D(f)

[H(f) = C(f) * S21(f)]

where:

X(f) = Measured input signal

Y(f) = Measured output signal

C(f) = Compression

S21(f) = Linear flatness and gain

D(f) = Output modulation distortion

Accessing the Distortion Measurement Parameters

How to select and configure Measurement Parameters

Using Hardkey / SoftTab / Softkey

1. Select a trace by pressing Trace > Trace N > Trace N.
2. Press Trace > Trace Setup > Measure....
3. Select a parameter.

Using a mouse

1. Right-click on a trace.
2. Select a parameter.

Main and Distortion Tab Measurement Parameters
Select from the parameters to measure power, S-parameters, or distortion characteristics.

**New Trace** - Add a new trace.

**Channel N** - Select a channel number for the new modulation distortion trace.

**Window N** - Select to create the new trace in an existing window or new window.

**Select All** - Select all measurement parameters.

The following tables describe the available Distortion Measurement Parameters for each DUT type and for the **Main** and **Distortion** tabs.

**Note:** The parameter names in the table assume we are testing a DUT with Port 1 = input and Port 2 = output.

**Main Tab Measurement Parameters**

Right-clicking on the dialog accesses a pop up menu. Select **Show Expert Tabs** to display the **Receivers** tab for selecting one of the VNA receivers:
Distortion Table

The Distortion Table is displayed below the measurement area. Each row represents a measurement band. Each column represents a measurement parameter.

<table>
<thead>
<tr>
<th>Type</th>
<th>Carrier 1 dBm</th>
<th>Carrier 3 dBm</th>
<th>Carrier 5 dBm</th>
<th>ACP 1 dBm</th>
<th>ACP 3 dBm</th>
<th>ACP 5 dBm</th>
<th>ACP Up 1 dBm</th>
<th>ACP Up 3 dBm</th>
<th>EVM %</th>
</tr>
</thead>
</table>

Total EVM

If there is more than one EVM band, then an extra band labeled **Total EVM** is added at the bottom of the table. The band power column sums the band power. The EVM and power density columns are a weighted average. The columns that do not apply are blank (for example, Carrier Offset Frequency).

Saving the Distortion Table

The Distortion Table can be saved to a .csv file in one of three ways:

1. Using a mouse, right-click in the Distortion Table area, select **Save Table As...**, then select **Distortion Table (*.csv)** from the **Save as type** pulldown menu in the **Save Data As** dialog.
2. Press **Save Recall > Save Other > Save Data...**, then select **Distortion Table (*.csv)** from the **Save as**
1. Type pulldown menu in the **Save Data As** dialog.

3. Using a mouse, select **Utility**, **Save**, **Save Data**, then select **Distortion Table (*.csv)** from the **Save as type** pulldown menu in the **Save Data As** dialog.

### Accessing Distortion Table

**Using Hardkey /SoftTab /Softkey**

| 1. Press **Meas > Main** > click the small button to the left of the **Distortion Table...** button. |

**Using a mouse**

| 1. Click **Instrument**. |
| 2. Select **Display**. |
| 3. Select **Show Table...**. |
| 4. In the **Customize Display** dialog, select the **Show Table** pull-down. |
| 5. Select **Distortion**. |
| 6. Click **OK**. |

### Distortion Table help

**Save Table As...**

Specifies the Modulation Distortion Table path and file name (*.csv).

| **Edit Columns...** |
| **Edit Rows...** |
| **Hide Table** |
| **Save Table As...** |

### Editing Columns

The columns may be edited by clicking on **Meas > Main > Distortion Table...** button or by right-clicking in the distortion table at the bottom of the measurement area to access the pop up menu then selecting **Edit Columns...**.
The Distortion Table Setup dialog is displayed with tabs for adding/removing measurement parameters for each measurement type.

**Show Table**

Check to display the Distortion Table at the bottom of the VNA display area.

**Sort Table By**

Select Band to sort the Distortion Table by band or Power to sort the Distortion Table by power.

**Font Size**

Select Small or Medium font size for the Distortion Table.

**Carrier tab**

![Carrier tab interface](image)

**EVM tab**
Editing Rows

The rows may be edited by right-clicking in the distortion table at the bottom of the measurement area to access the pop up menu then selecting **Edit Rows...**.

The **Modulation Distortion Setup Measure** tab dialog is displayed. Click on the **Measurement Type** pulldown menu then select **Multi-Band** to access the table for adding, editing, and deleting band rows. Learn more.

Buttons

**Defaults** - Resets the dialog to its default selections.

**MOD Setup...** - Accesses the **Modulation Distortion Setup Measure** tab dialog. Learn more.
Calibration Overview

Calibrating a Modulation Distortion channel requires the following types of calibrations:

- Phase Reference Wizard
- S-Parameter Calibration
- Receiver IF Cal
- Source Modulation Calibration

See Also

- Phase Reference Wizard (separate topic)
- S-Parameter Calibration (separate topic)
- Receiver IF Cal (separate topic)
- Source Modulation Calibration (separate topic)

Phase Reference Wizard

A Phase Reference Cal is performed, saved, and later recalled during a S-parameter calibration. This is sometimes referred to as a 'tier 1" calibration. Due to stability of the VNA, the Phase Reference Cal can be performed infrequently. It is typically performed over the full frequency range of the VNA or Phase Reference so that it can be applied to all modulation distortion calibrations that will be needed in the future.

S-Parameter Calibration

The S-parameter calibration with power correction is the traditional method used to compute linear error terms. Enhanced response terms are applied for correction since only the forward direction is measured. The a1, b1, and b2 waves for each tone are accurately measured with enhanced response correction. The calibration frequency range should cover all of the analysis bandwidth required for the Modulation Distortion channel.
**Receiver IF Cal**

Receiver IF Calibration is an additional process for S-parameter calibration in a Modulation Distortion channel to improve the error term in the IF chain of the VNA. Receiver IF Cal measures the S21 of the thru device at different IF frequencies to compute the correction coefficient.

**Source Modulation Calibration**

The source modulation calibration compensates the IQ data to achieve a flat frequency response in gain and phase at the reference plane. Before this calibration, the receivers must be calibrated by performing the S-parameter calibration. The DUT is connected at the reference plane when performing the source modulation calibration to achieve the best accuracy.
S-Parameter Calibration

Note: Perform this calibration before the Source Modulation Calibration.

The example procedure in this topic describes how to perform a typical calibration using the Cal All Calibration Wizard method, which allows multiple channel calibrations in a single session. For more information about this calibration method, refer to Calibrate All Channels.

1. Ensure that the Modulation Distortion measurement class to be calibrated is currently active.

2. Press Cal > Main > Cal All... to launch the following dialog showing the active measurement class:

![Calibration Dialog Example](image)

3. Select the ports.

4. Click Next, then confirm or change the calibration properties in the Measurement Class Cal Properties dialog:

![Measurement Class Properties Example](image)

5. Click Next to access the Calibration Attenuator Settings dialog:
6. In the **Calibration Attenuator Settings** dialog, perform the following:

   a. Set the attenuator settings. [Learn more.](#)

   b. Click on the **Noise Reduction** button to improve measurement accuracy. [Learn more.](#)

   c. Click on the **Mechanical Devices** button to view all switches and attenuators in the VNA. [Learn more.](#)

7. Click **Next**, then select the DUT connectors and calibration kits in the **Select DUT Connectors and Cal Kits** dialog.

8. Click **Next** to access the **Power Cal Settings** dialog.

9. In the **Power Cal Settings** dialog, set the desired Tolerance and Max Readings. Learn more about [Accuracy Tolerance](#) and [Max Number of Readings](#).
10. Click **Next** and follow the calibration process until completed.
Receiver IF Calibration is an additional process for S-parameter calibration in a Modulation Distortion channel to improve the error term of the IF chain of the VNA. Receiver IF Cal measures the S21 of the thru device at different IF frequencies to compute the correction coefficient. The S-parameter Cal Set contains all of these error terms. The point count used for the receiver IF cal is determined by the tone spacing of the modulated signal and the user’s measurement span.

The receiver IF calibration uses the internal PNA CW source to make the measurement.

Receiver IF Cal Procedure

Perform the Receiver IF Cal if it is inaccurate or missing. This will be indicated in the Receiver IF Cal dialog as a warning message. An inaccurate Receiver IF Cal occurs when the Start, Stop, Center, or Span setting frequencies do not match the active S-parameter Cal Set.

*Note:* The following procedure assumes the Receiver IF Cal has never been performed and is therefore not part of the active Cal Set.

1. Ensure that the Modulation Distortion measurement class to be calibrated is currently active.
2. Press **Cal** > **Cal Sets & Cal Kits** > **Cal Set...** then select a Cal Set to apply to the active channel.
3. Press **Cal** > **Main** > **Other Cals**.
4. Select **Receiver IF Cal...**. The following dialog is displayed:

The **Close** button aborts the calibration.

If **Do not show this dialog again** is checked, the Receiver IF Cal dialog will not be displayed when a calibration is required.

5. Click on the **Calibrate IF** button. The following dialog is displayed:
6. Connect a thru device between the input port and the output port (use a low loss, passive component).

7. Click on the **OK** button.

8. If the calibration was successful, the status message will indicate a valid IF calibration.
Source Modulation Calibration

**Note:** The calibration information in this topic applies to both the Option S93070xB Modulation Distortion and Option S9x09xxA/B, S9x090A/B Spectrum Analysis applications.

**Note:** For Option S93070xB Modulation Distortion, traditional S-parameter calibration using Cal All... must be performed before performing a Source Modulation Calibration. Cal All.. is not required for Option S9x09xxA/B, S9x090A/B Spectrum Analysis.

In this topic:

- Initiating the Calibration
- Modulation Cal - Setup Dialog Description
- Source Modulation Correction ON | OFF
- Example Calibration Procedure

### Initiating the Calibration

#### Accessing Source Modulation Cal - Option S93070xB Modulation Distortion Application

**Using Hardkey/SoftTab/Softkey**

1. Press **Cal > Main > Other Cals**.
2. Select **Source Modulation Cal...**.

**Using a mouse**

1. Click **Response**.
2. Select **Cal**.
3. Select **Other Cals**.
4. Select **Source Modulation Cal...**.
Accessing Source Modulation Cal - Option S9x09xxA/B, S9x090A/B Spectrum Analysis Application

Using **Hardkey/SoftTab/Softkey**

1. Press **Freq > Main > SA Setup...**.
2. Select the **Source** tab.
3. Click in the **IQMod** column for your external source then select **Edit**.
4. Click on the **Calibrate Modulation...** button.

**Note:** The calibration information is saved in the source modulation .mdx file and is enabled/disabled by the Source Modulation Correction ON/OFF selection.

**Cal Type** - Select the type of calibration to perform:

- **Power** calibrates the total output power of the carrier integrated over the signal span.
- **Equalization** performs a linear pre-distortion calibration which equalizes the magnitude and phase of the modulated signal. The Cal Span defaults to the occupied BW of the Carrier.
Signal.

**LO Feedthru** minimizes the LO feedthru tone. (LO feedthru tone may be changed after calibration. LO Feedthru monitor allows you to check the LO feedthru at every measurement)

**Distortion** minimizes the vector error of the modulation signal over the Cal Span. The Cal Span defaults to the occupied BW of the Carrier Signal.

> **Note:** An Equalization calibration is included when a Distortion calibration is performed.

**NPR Notch** nulls the NPR notch. The Cal Span defaults to the frequency range of the notch. If there are multiple notches having different spans, then Cal Span displays **Various**.

**ACP Upper/ACP Lower** nulls the ACP upper/lower sideband of the signal. The Cal Span is set to the frequency width of the ACP sideband being calibrated. The default Cal Span is equal to the carrier span.

> **Note:** The Cal Span may be set so high that the source cannot correct the signal. In this case, the Cal Span will be reduced automatically. The maximum span is 80% of the source sampling frequency.

**Cal Port** - Selects the calibration plane used for the calibration.

> **Note:** The Cal Port selections for Distortion, NPR, and ACP are coupled. Changing one selection will change them all.

**Cal Span** - Sets the span of the calibration.

**Guard Band** - (ACP Cal only) Sets the frequency delta from the edge of the carrier to the beginning of the Cal Span. The default is set to zero. This value is positive for both ACP Lower and ACP Upper.

> **Note:** The Guard Band may be set so high that the source cannot correct the signal. In this case, the Cal Span will be reduced automatically. In addition, it is possible to set the Guard Band so high that the Cal Span is set to zero, in which case the Guard Band will also be limited automatically.

**Max Iterations** - The calibration routine uses successive approximation. This value sets the maximum number of iterations used by the calibration routine.

**Desired Tolerance** - Sets the desired tolerance for each calibration.

**Save Cal in File** - Saves the modulation calibration to a file.
Mod Cal Details... button - Opens the Mod Cal Details dialog.

Enable Faster Cal with Reduced Accuracy - Check to perform a faster calibration.

Use Previous Cal as Initial Value - Check to start the successive approximation search algorithm for the calibration with previously measured data as the initial value to increase the
search speed. If the .mdx file contains a previous calibration, then that calibration will be used as the initial value. If there is no previous calibration in the .mdx file, but the calibration is being performed over multiple power levels, then the calibration at a previous power level will be used as the initial value. The default is checked.

**RF Power for calibration**:

- **Fixed** - Calibration is performed at a fixed power level.
  - **Cal Power** - Sets the fixed power level.
- **Swept** - Calibration is performed at multiple power levels.
  - **Start** Sets the beginning value of the power sweep.
  - **Stop** Sets the end value of the power sweep.
  - **Nmbr of Points** Sets the number of power points to calibrate during a sweep.

**RF Carrier for calibration**:

- **Fixed** - Calibration is performed at a fixed frequency.
  - **Cal Frequency** - Sets the fixed frequency.
- **Swept** - Calibration is performed at multiple frequencies.
  - **Start** Sets the beginning frequency value.
  - **Stop** Sets the end frequency value.
  - **Nmbr of Points** - Sets the number of frequency points to calibrate during a sweep.

**Note:** Several powers and several frequencies can be set up and the VNA will calibrate all combinations.

**VNA Status** - Displays a list of parameters and their settings.

**File Properties... button**

**Waveform Tab**

Displays the properties of the currently active modulation file, which was selected in the Modulation settings dialog. This information cannot be edited.
Calibration Tab

The Calibration tab displays the calibration files and their properties stored in the .mdx file. Each calibration displayed in the list is for one power level. Calibrations may have been performed on multiple power levels during a single calibration. In this case, multiple calibrations will be saved in the .mdx file. Any of these calibrations can be deleted by selecting the calibration name then clicking on the Delete Cal button.

Next> button- When pressed, the wizard checks to see if the selected filename contains an existing cal file. If it does, then the following warning message is displayed:

Overwrite Cal Data - Existing cal data will be overwritten.
**Append to Cal Data** - Keeps all existing cal data and appends only the data for the currently selected **Cal Type**. For example, if **LO Feedthru** is selected as the only **Cal Type** in the **Modulation Cal - Setup** dialog and the calibration is performed, only the LO Feedthru cal data will be updated and the cal data for all previous cals will remain unchanged. If you repeat the LO Feedthru calibration, and append to the file, it will replace the LO Feedthru cal while leaving the other calibrations (distortion, equalization, NPR, and ACPR) unchanged.

**Choose Different File** - Allows selection of a different cal file.

Accesses the **Modulation Cal - Measure** dialog:

![Modulation Cal - Measure](image)

**Calibrate** button - Starts the calibration.

**Display** - Select to display one of the following:

- **Desired Modulation** is the ideal simulated signal from the modulation file data.
- **Uncorrected Modulation** is the real-time measured signal without correction.
- **Corrected Modulation** is the real-time measured signal with correction.
- **Correction Terms** displays a static trace showing the correction terms applied.
to the modulation data.

**Calibration Iterations** displays multiple static traces used during the calibration.

If one or more of the default tolerance values could not be achieved, a warning message is displayed. You have the option to change the tolerance values and re-calibrate or save the current calibration.

![Warning message](image)

---

**Source Modulation Correction ON | OFF**

- Click on **Cal > Main > Src Mod Correct** to toggle between ON and OFF.

- ONLY correction for the Modulation Distortion channel is turned ON and OFF.

---

**Example Calibration Procedure**

The Source Modulation Cal procedure optimizes the signal across the pass band with the DUT connected. The following example describes how to perform a Source Modulation calibration for a typical setup using an N5182B MXG.

1. If you have the Option S93070xB Modulation Distortion Application installed, perform the following steps:
   a. From the **Modulate** tab, select the source with the **Source** pulldown menu.
   b. Load the **Modulation File** using the **Load File...** button.
   c. Click **Source Cal...** button.
2. If you have the Option S9x09xxA/B, S9x090A/B Spectrum Analysis Application installed, perform the following steps:
   a. Click on the **SA Setup...** button to open the **SA Setup** dialog then select the **Source** tab.
   
   b. Click in the **IQMod** column for your external source and select **Edit** to access the **Modulation settings** dialog.
   
   c. Load the **Modulation Filename**.
   
   d. Click on the **Calibrate Modulation...** button.

3. The **Modulation Cal - Setup** dialog is displayed.

4. Select **Power** check box to calibrate power across the entire pass band.
5. Select **Equalization** check box to perform a linear pre-distortion calibration.

6. Under **Cal Port** for **Power** and **Equalization**, select **DUT In Port 1** to calibrate the input side, or **DUT Out Port 2** to calibrate the output side (select a receiver for SA Analysis option). This will perform a calibration at the input or output of the DUT.

7. The default values for **Cal Span**, **Max Iterations** and **Desired Tolerance** will be used. Also, the default fixed power level will be used that is set using the **Mod Cal Details** dialog (-10 dBm).

8. Click **Next**. The following dialog is displayed.
9. Make the connections shown in the **Modulation Cal -Measure** dialog.

10. Click **Calibrate** to begin the calibration. When finished, the corrected modulated signal is displayed.

11. Click on the **Finish** button. If one or more of the default tolerance values could not be achieved, a warning message is displayed. You have the option to change the tolerance values and re-calibrate or save the current calibration.

12. The **Enable Source Correction** or **Enable Modulation Correction** check box is checked.

13. Click **OK**.
**Setup Examples**

The Option S9x070xB Modulation Distortion application measures the nonlinear behavior of an RF microwave amplifier and converters under a modulated signal.

A modulation file is created, uploaded to a signal generator, then fed into the VNA to test the behavior of the device by measuring band power, ACP, and EVM.

In this topic:

- Example Distortion Setup Procedure
- Physical Setup - Typical

  - Source Modulation Calibration

**Example Distortion Setup Procedure**

The following example describes how to set up a typical measurement using an N5182B MXG. In this example, a modulation file for a Compact modulation type is created. Compact signals cut a slice of the IQ data from an original waveform. Learn more.

1. Connect the equipment as shown after this procedure.
2. On the VNA front panel, press *Preset*.
3. Perform the following steps to set up an external MXG signal generator:
a. On the VNA front panel, press Setup > External Hardware > External Device...

b. Click on the New button.

c. Click in the Name field and type a name for the source. For example, myMXG.

d. For Device Type, select Source.

e. For the Driver, select MXG_Vector.

f. Select Active - Show in UI.

g. Ensure that Enable IO is checked.

h. In the I/O Configuration field, type the VISA address of the MXG.

i. Click on the OK button. The following is an example:

4. On the VNA front panel, press Meas > S-Param > Meas Class...

5. Select Modulation Distortion, then either:

   - OK delete the existing measurement, or

   - New Channel to create the measurement in a new channel.

6. The Modulation Distortion Setup dialog will be displayed.

7. Click on the Sweep tab and define the parameters as shown below:
8. Click on the **RF Path** tab and define the parameters as shown below:
Nominal Src Amp - If there is a loss between the MXG source output and Port 1 of the VNA, then use a negative number. This value is used for power calibration and to set the power level at the output of the DUT.

To access the Offsets and Limits dialog, click on the Offsets and Limits... button.

Nominal DUT Gain - This value is used for power calibration.

9. Click on the Modulate tab.
10. Select the MXG source from the **Source** pull down.

11. Click on the **Create...** button to access the **Create Modulation** dialog.
12. For the **Modulation Type**, ensure that **Compact** is selected from the pull down menu. This is the default selection.

13. Click on the "... " button to the right of the **Filename** field to load the original file from which to create a compact signal.

14. For **Signal Span**, use the default value.

15. For **Tone Spacing** and **Number of Tones**, use the default values.

16. For **DAC Scaling**, use the default value. For better S/N, increase the scaling value until a DAC overload occurs.

17. For **Frequency Tolerance**, use default value of 1 %.

18. Click on the **Calculate** button then verify that the signal is reasonable.

19. Click the **Save...** button and save the compact signal file. The filename is displayed below the display window.
20. In the Display pull down menu, select **Spectrum-Ideal**. Signals similar to the following should be displayed:

21. In the Display pull down menu, select **Time**. Signals similar to the following should be displayed:
22. In the Display pull down menu, select CCDF. Signals similar to the following should be displayed:

**CCDF**

Increasing the number of tones results in the following:

- Finer tone spacing.
- Longer period for the compact test signal.
- More accurate CCDF as shown below.
23. In the Create Modulation dialog, click **OK**.

24. Click on the **Measure** tab and define the parameters as shown below:

25. Selecting **ACP+EVM** measures band power, ACP, and EVM for the specified frequency settings in the **Measure** tab.

26. Click **OK**.

27. To make a measurement check without calibration, perform the following steps:
a. Make a Thru connection between the Pin and Pout reference planes.

b. Press Format > Format 1 > Log Mag then select dBm/Hz.

c. Press Scale > Main > Scale then set the scale to 10 dBm Per Division.

d. Press Reference Level then set it to -70 dBm.

e. Press Reference Position then set it to 10 Div.

f. Press Display > Display Setup > Show Table then select Distortion.

28. Note the following:

a. The Modulation Distortion channel makes multiple background sweeps to complete the measurement. During the measurement, the carrier frequency of the compact signal does not change, but the VNA local frequency changes to cover the SA span (300 MHz in this example). The result is stitched together and stored in the Modulation Distortion channel.

b. The Power Spectral Density (PSD) dBm/Hz at the reference plane is displayed.
c. The power level is not calibrated at this point. The result shown is based on the factory calibration of the receiver.
29. Refer to S-Parameter Calibration for a procedure on calibrating the VNA receivers.
30. After performing an S-parameter calibration, refer to Source Modulation Calibration for a procedure on calibrating source power and flatness.
31. After calibration, perform the following steps:
   a. Press Trace > Trace 1-7 > New Traces...
   b. In the New Trace dialog, select Pin1 (Power In), POut2 (Power Out) and MDist2 (Modulation Distortion Out).
   c. Change the format to dBm/Hz.
   d. Scale as needed.
   e. If the Distortion Table is not displayed, Press Display > Display Setup > Show Table then select Distortion.
32. The following is an example showing input signal and output signal measuring ACPR and EVM.

![Graph showing input and output signals with ACPR and EVM measurements.]

33. Add/remove parametric values by right-clicking in the distortion table at the bottom of the measurement area to access the pop up menu then selecting Edit Columns...

![Pop-up menu with options to edit columns, rows, or hide the table.]

34. Make desired selections from the Distortion Table Setup dialog.
Physical Setup - Typical

The following diagram shows a typical hardware setup using an N5182B MXG with the signal connected to the VNA rear-panel Port 1 J10 input connector.

**Note:** Though this example uses an N5182B MXG, an M8190A with E8267D PSG, or an M9383A MCS can be used as the external source.
**Key Parameters**

Frequency: 4.5 GHz

BW Signal: 100 MHz

Pin Max: -10 dBm at reference plane

SA Span: 300 MHz

**Physical Setup - High Power**

The following diagram shows a typical high power hardware setup using an M8190A with E8267D PSG with the signal connected to the VNA rear-panel Port 1 J10 input connector.
Key Parameters

Frequency: 28 GHz

BW Signal: 400 MHz

Pin Max: 10 dBm at reference plane

SA Span: 1.2 GHz

Physical Setup - External

The following diagram shows a typical external hardware setup using an M8190A with E8267D PSG with the signal connected externally.
Key Parameters

Frequency: 28 GHz

BW Signal: 400 MHz

Pin Max: 0 dBm at reference plane

SA Span: 1.2 GHz

Physical Setup - Converter

The following diagram shows a typical hardware setup using an N5182B MXG with the signal connected to the VNA rear panel Port 1 J10 input connector. Another method of connecting an N5182B MXG is with the signal connected to the VNA rear panel Port 1 J9 and connecting J10 to J11. This allows switching between the MXG and Source 1 without a mechanical switch.
**Key Parameters**

The Key Parameters are dependent upon the mixer setup and the measurement setup.

- Carrier Frequency
- Carrier Power
- SA Center/Span
- Noise BW
- LO Frequency
- LO Power
- Measurement Type
- Measurement Offset Frequency
- Measurement IBW

See https://www.keisight.com/find/m981xa-install/ for more detailed setup information.
Modulation Distortion Measurement

The procedures in this section describe how to set up and measure Modulation Distortion. The topics include:

- Hardware Setup for Amplifiers
- Hardware Setup for Converters
- Create a Modulation Distortion Channel
- Set Up a Sweep
- Set Up the RF Path
- Set Up a Converter
- Set Up the External Source
- Set Up Source3 Modulation Source - Option S93072B

- Set Up the Modulation File
  - Modulation File Overview
  - Set Up a Compact Modulation Type
  - Set Up a Flat Tones Modulation Type
  - Set Up a NPR Notch Modulation Type

- Set Up Modulation Distortion Measurements
  - Set Up an ACP Measurement
  - Set Up an EVM Measurement
  - Set Up a Band Power Measurement
  - Set Up a NPR Measurement
  - Set Up a Multi-Band Measurement
  - Set Up a Power Sweep Measurement
Hardware Setup for Amplifiers

A Vector Signal Generator is used to generate a repetitive signal with a given CCDF (Complementary-Cumulative-Distribution-Function) and PSD (Power Spectral Density).

Physical Setup - Typical

The following diagram shows a typical hardware setup using an N5182B MXG with the signal connected to the VNA rear-panel Port 1 J10 input connector.

Note: Though the following setup example uses an N5182B MXG, an M8190A with E8267D PSG, or an M9383A MCS can also be used as the external source.

Physical Setup - High Power

The following diagram shows a typical high power hardware setup using an M8190A with E8267D PSG with the signal connected to the VNA rear-panel Port 1 J10 input connector.
Hardware Setup for Converters

The following diagram shows a typical hardware setup using an N5182B MXG with the signal connected to the VNA rear panel Port 1 J10 input connector. Another method of connecting an N5182B MXG is with the signal connected to the VNA rear panel Port 1 J9 and connecting J10 to J11. This allows switching between the MXG and Source 1 without a mechanical switch.
Create a Modulation Distortion Channel

In this topic:

- Modulation Distortion Channel
- Modulation Distortion Converter Channel

Modulation Distortion Channel

1. On the VNA front panel, press **Meas > S-Param > Meas Class...**
2. Select **Modulation Distortion**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.
3. In the **Confirm Measurement Class Change** dialog, click **OK** to proceed or **Cancel** to exit.
4. The **Modulation Distortion Setup** dialog will be displayed.
5. The default Distortion Measurement Parameter is PIn1. This means that the displayed trace is the input power incident on the DUT. This setting is set using the DUT Input selection in the RF Path tab.

Modulation Distortion Converter Channel

1. On the VNA front panel, press Meas > S-Param > Meas Class....

2. Select Modulation Distortion Converters, then either:
   
   - OK delete the existing measurement, or
   
   - New Channel to create the measurement in a new channel.

3. In the Confirm Measurement Class Change dialog, click OK to proceed or Cancel to exit.

4. The Modulation Distortion Mixer Setup dialog is displayed.

5. The default Distortion Measurement Parameter is PIn1. This means that the displayed trace is the input power incident on the DUT. This setting is set using the DUT Input selection in the RF Path tab.
Set Up a Sweep

1. If the **Modulation Distortion Setup** dialog is not displayed, press **Freq > SA Frequency > MOD Setup**.

2. The **Sweep, RF Path, Modulate**, or **Measure** tab functions can now be selected.

3. Select the **Sweep** tab.

4. Select **Fixed** from the **Sweep Type** pull down menu. The **Fixed** sweep measures a modulated signal with a fixed carrier LO frequency and power level. A **Power** sweep can be selected which sweeps the total power of the modulated signal at multiple power levels defined by a start/stop power level. [Learn more.](#)

5. Set the **Carrier Frequency** by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This is dependent upon the frequency of the DUT.

6. Set the **SA Center** by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This sets the Spectrum Analyzer display center.

7. Set the **SA Span** by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This sets the Spectrum Analyzer (SA) display span. The following graphic shows the SA display set to the same center frequency as the Carrier and covering a span that includes the integrated bandwidth settings of ACPLo + Carrier + ACPUp.
8. Set the **Noise BW** by either using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. **Noise BW** is equal to the Resolution BW divided by the Vector Average factor.

9. Click on the **Sweep Details...** button to set the following:

   - **Force RF Power OFF at the End of Sweep - System Preference** - If enabled, RF power is turned off at the end of a sweep.

   - **Delay Before Start of Sweep** - Same as **Sweep Delay** in a standard channel.

   - **Delay Before Distortion Measurement** - Adds delay after the linear S-parameter sweep and before the distortion measurement to allow the RF source to settle.

   - **Enable S-Param Sweep** - Enables S-parameters to be measured at the low linear power level. If disabled (default), curve fitting (smoothing) is used instead of the S-parameter sweep. Curve fitting can be adjusted by varying the window aperture using the **Distortion Measurement Correlation Aperture** setting in the **Measurement Details** dialog.

   - **S-Param Source** - Selects source and signal used to measure S-parameters.

   - **External Vector - Chirp** - Selects a chirp signal from the external signal generator for measuring S-parameters.

   - **S-Param Power** - Sets the power level used at the DUT input to measure the DUT gain when operating in its linear region. The linear gain is used to calculate distortion.

   - **S-Param Freq Step** - Frequency step size setting used when measuring S-parameters.

   - **S-Param IFBW** - Bandwidth setting when measuring S-parameters.
Re-use Previous S-Parameter Measurements If Available - If disabled, S-parameters will be measured at the low linear power level. If enabled and compatible measurements exist from a previous sweep, those measurements will be used and a Linear S-parameter sweep will not be performed. If enabled and compatible measurements are not available, then a Linear S-parameter sweep will be performed.

10. Select the Set Power At pull down to set the power at either the DUT In or DUT Out. Adjust the power using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad.

11. To set up a power supply, click on the DC Sources... button which accesses the standard dialog for controlling power supplies. Learn more.

12. Click on the Apply button to apply the setting changes made in this dialog.
Set Up the RF Path

1. If the Modulation Distortion Setup dialog is not displayed, press Freq> SA Frequency > MOD Setup....

2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.

3. Select the RF Path tab.

4. To change the attenuation in the source path, check Include under the VNA Source Attenuator then use either up/down arrows or double-click in the data entry field and enter the attenuation using the displayed keypad. The source power level to the input of the attenuator will be adjusted based on the attenuation value to ensure the power level specified in the Sweep tab is provided at either the DUT In or DUT Out.

5. The Nominal Source Amp sets the nominal gain (positive number) from an amplifier, or loss (negative number) due to an attenuation, cable loss, etc. This function provides a method of compensating port power for added attenuation or amplification in the source path. This value is used by the Set Power At function, receiver leveling, and calibration. This value is equal to the Power Offset setting found on the Offsets and Limits dialog. For purposes of this example, assume there is no external source amplifier or attenuation. Since there is no need to account for gain or loss, the value should be set to 0 dB.

6. Select the DUT Input using the drop down menu then select the VNA port number connected to the DUT input.

7. Set the nominal DUT gain by clicking in the Nominal DUT Gain data entry field then using either the up/down
arrows or double-clicking in the data entry field and entering the gain using the displayed keypad. This value is used by Set Power At DUT Out, receiver leveling, and calibration. This function is also displayed on the calibration dialog.

8. Select the **DUT Output** using the drop down menu then select the VNA port number connected to the DUT output.

9. To change the receiver attenuation, under **Receiver Attenuator** use either the up/down arrows or double-click in the data entry field and enter the attenuation using the displayed keypad.

10. Click on the **Path Configuration...** button and ensure that the correct RF path is selected according to the Hardware Setup then click **OK**. For this example, the Combiner path for Port 1 is selected since the modulated signal is connected to the rear-panel J10 connector.

11. Click on the **Apply** button to apply the setting changes made in this dialog.
Set Up a Converter

For purposes of these examples, only 1 converter stage will be configured.

In this topic:

- Procedure for Converter without Embedded LO
- Procedure for Converter with Embedded LO

Procedure for Converter without Embedded LO

1. If the Modulation Distortion Setup dialog is not displayed, press **Freq** > **SA Frequency** > **MOD Setup**.

2. The **Sweep**, **RF Path**, **Mixer**, **Modulate**, or **Measure** tab functions can now be selected.

3. Select the **Mixer** tab.

4. In the **Converter Stages** pull down menu, select 1.
5. Click on the **Source Name** pull down menu then select **Port 3**. This is the LO source.

6. Adjust the **Power** using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad.

7. Click on the **Leveling** pull down menu then select **Open Loop** or **Internal**. The **Open Loop** selection does not use ALC or receiver leveling. The **Internal** selection uses ALC leveling.

8. Adjust the receiver **Attenuator** using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad.

9. Adjust the **LO** frequency using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad.

10. Set the multiplier and denominator. The combination of numerator / denominator forms a fractional value that is multiplied by the input and LO frequency ranges. [Learn more.](#)

11. Adjust the **Input** using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This is the same as **Carrier Freq In** in the **Sweep** tab.

12. Click on the Output equation pull down menu then select the mixer configuration calculated from the output mixer equation selection.

13. To save the mixer setup, click on the **Save...** button then enter the file name and directory path.

### Procedure for Converter with Embedded LO

The following procedure describes how to set up measurements of mixers that have a fixed LO inside the DUT.

1. If the **Modulation Distortion Setup** dialog is not displayed, press **Freq > SA Frequency > MOD Setup**....

2. The **Sweep**, **RF Path**, **Mixer**, **Modulate**, or **Measure** tab functions can now be selected.

3. Select the **Mixer** tab.
4. In the **Converter Stages** pull down menu, select 1.

5. Adjust the **LO** frequency using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad.

6. Set the multiplier and denominator. The combination of numerator / denominator forms a fractional value that is multiplied by the input and LO frequency ranges. Learn more.

7. Adjust the **Input** using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This is the same as **Carrier Freq In** in the **Sweep** tab.

8. Click on the **Output equation** pull down menu then select the mixer configuration calculated from the output mixer equation selection.

9. Click on the **Setup...** button. The **Embedded LO** dialog is displayed:
10. Check the **Enable Embedded LO** check box.

11. Click on the **Tuning Method** pull down menu. These settings determine the amount of time spent versus the degree of accuracy to which the LO Frequency is measured. Accuracy is compromised when noise starts to appear on the measurement trace. Select from the following:

   - **Broadband and Precise** Does the entire tuning process for each background sweep.

   - **Precise Only** Does NOT perform broadband tuning on each sweep. Use this setting when the embedded LO is stable. The signal (after broadband) must be within $\frac{1}{2}$ the tuning IFBW. If the signal will always be within $\frac{1}{2}$ the IFBW, broadband tuning is not needed.

   - **Disable Tuning** Only the previously measured **LO Frequency Delta** is applied to the reference mixer LO and VNA receivers.

12. Set the **Tune every** interval at which tuning is performed before a measurement sweep using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. For
example, 'Tune every 3 sweeps' means that every third measurement sweep is preceded by tuning sweeps.
If the embedded LO drifts, or if regularly changing DUTs, set it to 'Tune every 1 sweep'.

13. Set the **Broadband Search** frequency span over which to measure the embedded LO frequency using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad.

14. Set the **Noise BW** used for Broadband and Precise tuning sweeps using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. This sets the resolution in the Broadband sweeps.

15. Set the **Max Iterations** of Precise sweeps to make using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. When this number is reached, the final measurement is used.

16. Set the **Tolerance** using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. When two consecutive Precise measurements are made within this value, the final measurement is used. If this is not achieved within the Max Iterations value, then the last measurement is used.

17. Click on the **Find Now** button to find and measure the actual LO frequency using the current dialog settings. This data is displayed in the **Status** box.

18. The **LO Frequency Delta** displays the absolute difference between the measured embedded LO frequency and the LO setting that is entered in the Mixer Tab dialog.

19. Click on the **OK** button.

20. In the **Mixer** tab, click on the **Apply** button to apply the settings.

21. To save the mixer setup, click on the **Save...** button then enter the file name and directory path.
Set Up the External Source

Perform the following steps to set up an external MXG signal generator:

**Note:** If you are setting up an M8190A Arbitrary Waveform Generator with E8267D PSG Vector Signal Generator, refer to [Drivers for External Compound Sources](#) for information about setting up compound sources.

1. On the VNA front panel, press **Setup > External Hardware > External Device....**
2. Click on the **New** button.
3. Click in the **Name** field and type a name for the source. For example, **myMXG**.
4. For **Device Type**, select **Source**.
5. For the **Driver**, select **MXG_Vector**. See a list of supported external source drivers.
6. Select **Active - Show in UI**.
7. Ensure that **Enable IO** is checked.
8. In the **I/O Configuration** field, type the VISA address of the MXG.
9. Click on the **OK** button. The following is an example:

![External Device Configuration: myMXG](image)
Set Up Source3 Modulation Source - Option S93072B

Option S93072B Arbitrary Waveform Generation on XSB Port (requires Option S93072B, Option XSB, Option S93070xB or Sx090A/B, and either Option 422 or Option 423) allows you to generate arbitrary waveforms including multitone signals.

The following PNA-X block diagram shows Option XSB with Option 423.

Source3 Setup Limitations

Sample Rate

Allowed sample rate values are integer divisors of 19.2 GHz from 19.2 GHz to 1 MHz.

Signal Span

Allowed signal span is 1 MHz to 6 GHz.

Tone Spacing/Waveform Period

Waveform Period can be from 1.666 nsec to 6.822 microseconds in multiples of 1.666 nsec. The waveform memory limitation is $2^{17}$ or 128k and the waveform length must be a multiple of 32. That is, the tone spacing of the underlying waveform must be 600 MHz/N where N is 1 to 4096.
Carrier Frequency

Signal Span/2 <= Carrier Frequency <= (6 GHz - Signal Span/2)

The carrier must land on the tone spacing grid:

- For odd number of tones, Carrier Frequency = \( N \times \text{Tone Spacing} \)
- For even number of tones, Carrier Frequency = \( N \times (\text{Tone Spacing})/2 \), where \( N \) is odd.

Select Source3 in Create Modulation Dialog

1. If the Modulation Distortion Setup dialog is not displayed, press Freq > SA Frequency > MOD Setup... .
2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.
3. Select the Modulate tab.
4. In the Modulate tab, click on the Create... button to access the Create Modulation dialog.
5. In the **Modulation Type** pull down menu, select the desired modulation type.

6. In the **Source Name** pull down menu, select **Source3**.

7. For the remainder of the setup, refer to the procedure corresponding to the **Modulation Type** selection in Step 5.

   - Set Up a Compact Modulation Type
   - Set Up a Flat Tones Modulation Type
   - Set Up a NPR Notch Modulation Type
Set Up the Modulation File

The procedures in this section describe how to set up the Modulation Files. The topics include:

- Modulation File Overview
- Set Up a Compact Modulation Type
- Set Up a Flat Tones Modulation Type
- Set Up a NPR Notch Modulation Type
Modulation File Overview

Modulation files are created then loaded into the source. The modulation files created using the Create Modulation dialog include Flat Tones, NPR Notch, and a shortened version of a modulation file called Compact.

When viewed in the frequency domain, this signal is a mult-tone "grid" of frequencies. The data is measured on this multi-tone grid.

Compact Modulation Type

Compact test signals cut a slice of the IQ data from an original parent signal created using Keysight Signal Studio or created using a .csv file. The slice of IQ data is chosen that best fits in terms of statistical distribution (CCDF), then conditions the waveform so that it has the same spectrum signature as the original signal.
Keysight Signal Studio Waveform (.wfm)

The Keysight Signal Studio Software can be used to create the original parent signal in a .wfm file format for a compact modulation type measurement.

In order to use a compact file (.mdx) which is created from .wfm, the corresponding license is required on the Signal Generator to play the .mdx.

When the waveform pack license is used, the original waveform file must be assigned / locked to the signal generator in order to use the .mdx created from the original waveform file.

Note: Encrypted .wfm files created using the N5182B MXG RF Vector Signal Generator are not supported.

IQ File (.csv)

The original parent file can also be created using a .csv file format that has a timestamp, I, and Q that uses a comma to separate the values.

No license is required on the signal generator to play the .mdx created from the .csv.

Flat Tones Modulation Type

Flat tones are used to measure the frequency response of a device with a single input signal. This allows the gain and electrical delay through the device to be measured.

A modulated communications signal such as 5G NR or OFDM, when plotted versus frequency, is not a set of flat tones. It is relatively flat, but some tones may be very small (near zero). So those signals are not as useful for measuring gain and electrical delay, although it can be done by ignoring noisy data and smoothing.

It is possible to measure distortion (EVM and ACP) using flat tones. The creation of flat tones is
provided because it is very simple and is useful.

- Flat tones are often used with satellites (which are complicated converters):
  - Users are less concerned about communications formats and EVM.
  - Users are interested in gain and electrical delay through their device.
- Flat tones may also be used with any amplifier/converter:
  - Measure gain and electrical delay and EVM/ACP.
  - Make measurements using Modulation Distortion or Modulation Distortion Converters application.

### NPR Notch Modulation Type

NPR Notch modulation type is a Noise Power Ratio measurement. The notch is created where no signals are present. The location and span of the notch is set by the user. With the stimulus applied to the DUT, the ratio of the noise power of the carrier to the noise power in the notch is measured.
Set Up a Compact Modulation Type

1. If the **Modulation Distortion Setup** dialog is not displayed, press **Freq > SA Frequency > MOD Setup...**.

2. The **Sweep**, **RF Path**, **Modulate**, or **Measure** tab functions can now be selected.

3. Select the **Modulate** tab.

4. In the **Modulate** tab, click on the **Create...** button to access the **Create Modulation** dialog.
5. In the **Modulation Type** pull down menu, select **Compact**.

6. In the **Source Name** pull down menu, select the source. If it is not in the list, select **Add Source...** then refer to Set Up the External Source to set up a source.

7. In the **Filename** field, click on the "... " button to the right of this field and load the original (parent) signal file. The compact test signal will be based on this original signal and is generated automatically. The input waveforms are created using Signal Studio or IQ files in *.csv format. The resultant compact test signal version of the waveform matches the CCDF and PSD of the "parent-IQ waveform".

8. The settings under **Compact Signal** are filled in based on the original signal.

9. Click on the **Calculate** button then under **Calculated Result**, verify that the signal looks reasonable.

10. To make adjustments to the settings, perform the following procedure (optional):

   a. Set the **Number of Files** to 2 using the up arrow. This function is useful to create several signals, compare them, then save the best signal.

   b. To adjust the frequency span of the modulated carrier, click in the **Signal Span** data entry field then use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

   c. To adjust the distance between each tone, click in the **Tone Spacing** data entry field then use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.
d. To adjust the number of tones, click in the **Number of Tones** data entry field then use the up/down arrows to make a change. Increasing the number of tones increases the CCDF accuracy.

e. To adjust the carrier offset value relative to the carrier LO frequency, click in the **Carrier Offset** data entry field then use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

f. To define a multicarrier signal, select 2, 3, 4, 5, 6, 7, 8, or 9 from the **Nmbr of Subcarriers** pull-down menu then set the corresponding **SubN Span** and **SubN Offset** (where "N" is the subcarrier number).

g. To adjust the the scaling factor used for the waveform (full scale = 100%), click in the **DAC Scaling** data entry field then use the up/down arrows or double-click in the data entry field then enter the value using the displayed keypad. This ensures that the DAC filter does not output a signal that is larger than the DAC's maximum output level, which can cause distortion in the system. Setting the scaling factor to 100% will usually cause excessive distortion.

h. To adjust where to start the compact signal within the original signal, check the **Priority** check box for **Signal Start Time**, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the start time using the displayed keypad.

i. With the **Enable Optimizer** check box checked, the calculated modulated signal will be optimized according to the constraints defined in **Optimize Signal** group box. For more information, refer to the description for Enable Optimizer and the Optimizer Setup dialog.

j. To adjust the allowed tolerance for tone spacing when calculating the modulation signal, select **Frequency Tolerance** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the tolerance using the displayed keypad.

k. To adjust minimum period of the waveform greater than or equal to the specified value (seconds), select **Min Waveform Period** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the period using the displayed keypad.

l. To adjust minimum number of tones greater than or equal to the specified value, select **Min Number of Tones** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the number of tones using the displayed keypad. This will ignore the **Number of Tones** selection.

m. To adjust maximum tone spacing less than or equal to the specified value (Hz), select **Max Tone Spacing** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the maximum tone spacing using the displayed keypad. This will ignore the **Tone Spacing** selection.

n. After making any adjustments, click on the **Calculate** button then, under **Calculated Result**, verify that the signal looks reasonable.

o. Use the **File** pull down menu to switch between the first and second file for comparison.

p. Choose the best signal.
11. Click the **Save**... button and save the compact test signal file. The filename is displayed below the display window.

![Image of Create Modulation window](image1)

12. In the **Display** pull down menu, select **Spectrum-Ideal**. Signals similar to the following should be displayed:

![Image of Spectrum-Ideal](image2)

13. In the **Display** pull down menu, select **Time**. Signals similar to the following should be displayed:
14. In the **Display** pull down menu, select **CCDF**. The following plot represents the complementary cumulative distribution function (CCDF) curve of the original (parent) signal, compact test signal, as well as the Gaussian distribution (pink trace):

15. Increasing the number of tones results in the following:

- Finer tone spacing.
- Longer period for the compact test signal.
- More accurate CCDF as shown below.
16. Click on the **OK** button. The modulation file is uploaded to the external source.

17. The **Autofill Measurements** message is displayed asking whether to autofill measurement frequencies or not. These frequencies are in the **Measure** tab. Learn more.

18. Click **Yes**.
Set Up a Flat Tones Modulation Type

1. If the **Modulation Distortion Setup** dialog is not displayed, press **Freq > SA Frequency > MOD Setup...**.

2. The **Sweep**, **RF Path**, **Modulate**, or **Measure** tab functions can now be selected.

3. Select the **Modulate** tab.

4. In the **Modulate** tab, click on the **Create...** button to access the **Create Modulation** dialog.
4. In the Modulation Type pull down menu, select Flat Tones.

5. In the Source Name pull down menu, select the source. If it is not in the list, select Add Source... then refer to Set Up the External Source to set up a source.

6. Click on the Calculate button then under Calculated Result, verify that the signal looks reasonable.

7. To make adjustments to the settings, perform the following procedure (optional):

   a. To adjust the frequency span of the modulated carrier, click in the Signal Span data entry field then
use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

b. To adjust the distance between each tone, click in the **Tone Spacing** data entry field then use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

c. To adjust the number of odd or even tones, select either **Nmbr Tones, Odd** or **Nmbr Tones, Even**, click in the data entry field, then use the up/down arrows to make a change. This setting forces the optimizer to choose an odd or even number of tones. The optimizer will also choose an offset such that the carrier lands on one of the tones.

d. To adjust the carrier offset value relative to the carrier LO frequency, click in the **Carrier Offset** data entry field then use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

e. To select a phase type, click on the **Phase Type** pull down menu then select **Random**, **Fixed**, or **Parabolic**. The **Random Phase Seed** sets the phase seed when **Random** phase is the **Phase Type**.

f. To adjust the the scaling factor used for the waveform (full scale = 100%), click in the **DAC Scaling** data entry field then use the up/down arrows or double-click in the data entry field then enter the value using the displayed keypad. This ensures that the DAC filter does not output a signal that is larger than the DAC's maximum output level, which can cause distortion in the system. Setting the scaling factor to 100% will usually cause excessive distortion.

g. With the **Enable Optimizer** check box checked, the calculated modulated signal will be optimized according to the constraints defined in **Optimize Signal** group box. For more information, refer to the description for Enable Optimizer and the Optimizer Setup dialog.

h. To adjust the allowed tolerance for tone spacing when calculating the modulation signal, select **Frequency Tolerance** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the tolerance using the displayed keypad.

i. To adjust minimum period of the waveform greater than or equal to the specified value (seconds), select **Min Waveform Period** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the period using the displayed keypad.

j. To adjust minimum number of tones greater than or equal to the specified value, select **Min Number of Tones** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the number of tones using the displayed keypad. This will ignore the **Number of Tones** selection.

k. To adjust maximum tone spacing less than or equal to the specified value (Hz), select **Max Tone Spacing** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the maximum tone spacing using the displayed keypad. This will ignore the **Tone Spacing** selection.

l. After making any adjustments, click on the **Calculate** button then, under **Calculated Result**, verify that the signal looks reasonable.
9. Click the **Save...** button and save the flat tone file. The filename is displayed below the display window.

![Calculated Result](image1)

10. In the **Display** pull down menu, select **Spectrum-Ideal**. Signals similar to the following should be displayed:

![Spectrum-Ideal](image2)

11. In the **Display** pull down menu, select **Time**. Signals similar to the following should be displayed:
12. In the Display pull down menu, select **CCDF**. The following plot represents the complementary cumulative distribution function (CCDF) curve of the flat tones test signal, as well as the Gaussian distribution (pink trace):

![Plot of flat tones and Gaussian distribution](image)

13. Increasing the number of tones results in the following:

- Finer tone spacing.
- Longer period for the test signal.
- More accurate CCDF as shown below.
14. Click on the **OK** button. The modulation file is uploaded to the external source.

15. The **Autofill Measurements** message is displayed asking whether to autofill measurement frequencies or not. These frequencies are in the **Measure** tab. Learn more.

16. Click **Yes**.
Set Up a NPR Notch Modulation Type

1. If the Modulation Distortion Setup dialog is not displayed, press Freq > SA Frequency > MOD Setup...

2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.

3. Select the Modulate tab.

4. In the Modulate tab, click on the Create... button to access the Create Modulation dialog.
5. In the **Modulation Type** pull down menu, select **NPR Notch**.

6. In the **Source Name** pull down menu, select the source. If it is not in the list, select **Add Source...** then refer to Set Up the External Source to set up a source.

7. Click on the **Calculate** button then under **Calculated Result**, verify that the signal looks reasonable.

8. To make adjustments to the settings, perform the following procedure (optional):

   a. To adjust the frequency span of the modulated carrier, click in the **Signal Span** data entry field then
use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

b. To adjust the distance between each tone, click in the **Tone Spacing** data entry field then use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

c. To adjust the number of odd or even tones, select either **Nmbr Tones, Odd** or **Nmbr Tones, Even**, click in the data entry field, then use the up/down arrows to make a change. This setting forces the optimizer to choose an odd or even number of tones. The optimizer will also choose an offset such that the carrier lands on one of the tones.

d. To adjust the carrier offset value relative to the carrier LO frequency, click in the **Carrier Offset** data entry field then use the up/down arrows or double-click in the data entry field then enter the frequency using the displayed keypad.

e. To select a phase type, click on the **Phase Type** pull down menu then select **Random**, **Fixed**, or **Parabolic**. The **Random Phase Seed** sets the phase seed when **Random** phase is the **Phase Type**.

f. To set the number of notches, select the **Nmbr of Notches** pull down menu and select up to 3 notches.

g. To set the notch location, select the **Notch Location** pull down menu and select **Custom**, **Symmetric**, or **Avoid Carrier**.

- **Custom** selection allows the user to define the notch span using **Notch1 Span** and notch offset using **Notch1 Offset**.

- **Symmetric** selection locates the notch in the center of the **Signal Span** and allows the notch span to be changed using **Notch1 Span**.

- **Avoid Carrier** selection locates the notch near the center of the **Signal Span** but will be shifted to avoid the LO carrier feedthrough and allows the notch span to be changed using **Notch1 Span**.

h. To adjust the the scaling factor used for the waveform (full scale = 100%), click in the **DAC Scaling** data entry field then use the up/down arrows or double-click in the data entry field then enter the value using the displayed keypad. This ensures that the DAC filter does not output a signal that is larger than the DAC's maximum output level, which can cause distortion in the system. Setting the scaling factor to 100% will usually cause excessive distortion.

i. With the **Enable Optimizer** check box checked, the calculated modulated signal will be optimized according to the constraints defined in **Optimize Signal** group box. For more information, refer to the description for Enable Optimizer and the Optimizer Setup dialog.

j. To adjust the allowed tolerance for tone spacing when calculating the modulation signal, select **Frequency Tolerance** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the tolerance using the displayed keypad.
k. To adjust minimum period of the waveform greater than or equal to the specified value (seconds), select **Min Waveform Period** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the period using the displayed keypad.

l. To adjust minimum number of tones greater than or equal to the specified value, select **Min Number of Tones** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the number of tones using the displayed keypad. This will ignore the **Number of Tones** selection.

m. To adjust maximum tone spacing less than or equal to the specified value (Hz), select **Max Tone Spacing** from the **Optimize Signal** pull down menu, click in its data entry field, then use the up/down arrows or double-click in the data entry field then enter the maximum tone spacing using the displayed keypad. This will ignore the **Tone Spacing** selection.

n. After making any adjustments, click on the **Calculate** button then, under **Calculated Result**, verify that the signal looks reasonable.

9. Click the **Save...** button and save the NPR Notch file. The filename is displayed below the display window.

![Calculated Result](image)

10. In the **Display** pull down menu, select **Spectrum-Ideal**. Signals similar to the following should be displayed:
11. In the **Display** pull down menu, select **Time**. Signals similar to the following should be displayed:

![Time signal](image1)

12. In the **Display** pull down menu, select **CCDF**. The following plot represents the complementary cumulative distribution function (CCDF) curve of the NPR Notch test signal, as well as the Gaussian distribution (pink trace):

![CCDF plot](image2)

13. Increasing the number of tones results in the following:
- Finer tone spacing.
- Longer period for the test signal.
- More accurate CCDF as shown below.

Number of Tones = 1,001

Number of Tones = 10,001

14. Click on the **OK** button. The modulation file is uploaded to the external source.

15. The **Autofill Measurements** message is displayed asking whether to autofill measurement frequencies or not. These frequencies are in the **Measure** tab. Learn more.

16. Click **Yes**.
Set Up Modulation Distortion Measurements

The procedures in this section describe how to set up Modulation Distortion measurements. The topics include:

- Set Up an ACP Measurement
- Set Up an EVM Measurement
- Set Up a Band Power Measurement
- Set Up a NPR Measurement
- Set Up a Multi-Band Measurement
- Set Up a Power Sweep Measurement
Set Up an ACP Measurement

ACP (Adjacent Channel Power) measures the channel power of the lower and upper adjacent channel band. DUT input and output ACP can be measured as well as the DUT contribution.

In this topic:

- ACP Measurement Criteria
- Upper and Lower Side Bands of the Input and Output Signal
- Upper and Lower Side Bands Contribution of the DUT

ACP Measurement Criteria

The procedures in the list below must be performed prior to making ACP measurements. For purposes of this example, the DUT used is an amplifier and the Modulation Type is Flat Tones.

- Required set up procedures:
  - Hardware Setup for Amplifiers
  - Create a Modulation Distortion Channel
  - Set Up a Sweep
  - Set Up the RF Path
  - Set Up the External Source
  - Set Up a Flat Tones Modulation Type
Calibration procedures:
- Phase Reference Wizard
- S-Parameter Calibration
- Receiver IF Cal
- Source Modulation Calibration

Upper and Lower Side Bands of the Input and Output Signal

1. If the Modulation Distortion Setup dialog is not displayed, press **Freq > SA Frequency > MOD Setup...**.

2. The **Sweep**, **RF Path**, **Modulate**, or **Measure** tab functions can now be selected.

3. Select the **Measure** tab.

4. In the **Measurement Type** pull down menu, select **ACP**.
5. Click on the **Autofill** button to automatically fill in the measurement settings for all bands from the currently active modulation file loaded in the source. Therefore, changing the settings in the following steps is optional.

6. To offset the Carrier integration bandwidth relative to the Carrier LO used to generate the modulation signal, use the up/down arrows in the **Carrier Offset Freq** field or double-click in the field then enter the value using the displayed keypad.

7. To set the Carrier integration bandwidth for the distortion measurement, use the up/down arrows in the **Carrier Integ BW** field or double-click in the field then enter the value using the displayed keypad. The IBW is used to determine total signal power within a specified frequency span.

8. To offset the lower ACP integration bandwidth relative to the LO used to generate the modulated signal, use the up/down arrows in the **ACPLo Offset Freq** field or double-click in the field then enter the value using the displayed keypad.

9. To set the integration bandwidth of the lower ACP measurement, use the up/down arrows in the **ACPLo Integ BW** field or double-click in the field then enter the value using the displayed keypad. The IBW is used to determine total signal power of the lower ACP within a specified frequency span.

10. To offset the upper ACP integration bandwidth relative to the LO used to generate the modulated signal, use the up/down arrows in the **ACPUp Offset Freq** field or double-click in the field then enter the value using the displayed keypad.

11. To set the integration bandwidth of the upper ACP measurement, use the up/down arrows in the **ACPUp Integ BW** field or double-click in the field then enter the value using the displayed keypad. The IBW is used to determine total signal power of the upper ACP within a specified frequency span.
12. To adjust other measurement settings, click on the Measurement Details... button:

![Measurement Details dialog](image)

a. To set the frequency span window used for modeling the DUT’s gain and distortion, use the up/down arrows in the Distortion Measurement Correlation Aperture field or double-click in the field then enter the value using the displayed keypad. Checking Auto will automatically set Distortion Measurement Correlation Aperture to window size.

b. To select the IF filter anti-aliasing path, click on the ADC Anti-alias Filter pull down menu then select Auto, Wide, or Narrow. Auto will automatically set the ADC Filter setting based on the ADC Sampling Frequency. If the currently selected modulation waveform was created with Nyquist Rejection = OFF, then the VNA will measure the signal using the Narrow anti-alias filter in the receiver. Wide selects the ADC 38 MHz IF filter path. Narrow selects the ADC 11 MHz IF filter path. A warning message will appear if the Narrow IF filter path is selected and the Resolution Bandwidth is > 1 MHz.

c. To set the measurement filter to either None (default) or RRC (root-raised-cosine filter), click on the Modulation Filter pull down menu then make the selection. With RRC selected, Alpha sets the Alpha factor of the filter and Symbol Rate sets the Symbol Rate of the filter. If Auto is selected, the Symbol Rate will be approximated from the bandwidth of the signal.

d. Click on the OK button.

13. Click on the Apply button to apply the setting changes made in this dialog.

14. Click on the OK button to close the dialog.

15. Ensure that the VNA Trigger is set to Continuous. Press Trigger > Main > Continuous.

16. The Distortion Table is displayed below the measurement area. Each column represents a measurement parameter. The measurement parameters shown in the Distortion Table below are the default parameters.
selected for an ACP measurement.

<table>
<thead>
<tr>
<th>Type</th>
<th>Carrier In1 dBm</th>
<th>Carrier Out2 dBm</th>
<th>Carrier Gain21 dB</th>
<th>Carrier IBW</th>
<th>ACP LowIn1 dBc</th>
<th>ACP LowOut2 dBc</th>
<th>ACP UpIn1 dBc</th>
<th>ACP UpOut2 dBc</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACP</td>
<td>-20.85 dBm</td>
<td>-7.85 dBm</td>
<td>13.00 dB</td>
<td>100.1 MHz</td>
<td>-44.83 dBc</td>
<td>-53.65 dBc</td>
<td>-45.17 dBc</td>
<td>-53.66 dBc</td>
</tr>
</tbody>
</table>

17. The measurement parameters are selected using the Distortion Table Setup dialog. To add or change parameters, press *Meas > Main > Distortion Table...* or right-click on the Distortion Table displayed below the measurement area then select *Edit Columns...* in the pop-up menu. The *Distortion Table Setup* dialog is displayed:

![Distortion Table Setup dialog](image)

18. Select the **ACP** tab.
19. Check the desired measurement parameters then click on the **OK** button.

20. To view traces displaying the ratio of upper and lower side bands of the input and output signal, perform the following:

   a. Press **Meas** > **Main** > **Other**... then click on the "..." button. The **Measure** dialog is displayed:
b. Select the **Distortion** tab to display distortion traces:
c. To display a trace measuring the ratio of upper and lower side bands of the input signal, check ACPIn1 then click on the Apply button.

d. In the Distortion tab, check New trace.

e. To display a trace measuring the ratio of upper and lower side bands of the output signal, check ACPOut2 then click on the OK button.

21. The following is an example of a typical trace and Distortion Table showing the ACP lower and upper input/output:

![Typical trace and Distortion Table](image)

**Upper and Lower Side Bands Contribution of the DUT**

After setting up and performing an ACP measurement as described in the above procedure, perform the following procedure to measure the distortion contribution by the DUT.

1. Press Meas > Main > Distortion Table... or right-click on the Distortion Table displayed below the measurement area then select Edit Columns... in the pop-up menu.

2. In the Distortion Table Setup dialog, select the ACP tab.
3. Check the **ACP LoDist21 dBc** (lower side added by DUT) and **ACP UpDist21 dBc** (upper side added by DUT) parameters then click on the **OK** button. The added parameters are displayed as a new column in the Distortion Table displayed below the measurement area.

4. To view a trace displaying the distortion contribution by the DUT, perform the following:

   a. Press **Meas > Main > Other...** then click on the " ... " button. The **Measure** dialog is displayed:
b. Select the **Distortion** tab to display distortion traces:
c. In the **Distortion** tab, check **New trace**. If any parameters are currently checked, uncheck them.

d. Check **ACPDist21** then click on the **Apply** button.

e. If necessary, press **Scale > Main > Scale Coupling ...**, select **Window** as the **Coupling Method**, then click **OK**. This re-scales all traces to the same scale.

f. Click on the **Autoscale All** softkey.

5. The following is an example of a typical trace and Distortion Table showing the lower and upper contributions by the DUT:
Set Up an EVM Measurement

To compute EVM, the input and output response of the DUT in the frequency domain is measured. Spectrum correlation is then performed to compute the EVM. The procedures in this topic describe how to measure the equalized EVM of the DUT (non-linear contribution) and the un-equalized EVM of the DUT (Includes non-linear and linear distortion due to frequency dispersion).

In this topic:

- EVM Measurement Criteria
- Equalized EVM of the DUT (non-linear contribution)
- Un-equalized EVM of the DUT (Includes non-linear and linear distortion due to frequency dispersion)

EVM Measurement Criteria

The procedures in the list below must be performed prior to making EVM measurements. For purposes of this example, the DUT used is an amplifier and the Modulation Type is Flat Tones.

- Required set up procedures:
  - Hardware Setup for Amplifiers
  - Create a Modulation Distortion Channel
  - Set Up a Sweep
  - Set Up the RF Path
  - Set Up the External Source
  - Set Up a Flat Tones Modulation Type

- Calibration procedures:
  - Phase Reference Wizard
  - S-Parameter Calibration
  - Receiver IF Cal
  - Source Modulation Calibration

Equalized EVM of the DUT (non-linear contribution)

1. If the Modulation Distortion Setup dialog is not displayed, press Freq > SA Frequency > MOD Setup...

2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.

3. Select the Measure tab.
4. In the **Measurement Type** pull down menu, select **EVM**.
5. Click on the Autofill button to automatically fill in the measurement settings for all bands from the currently active modulation file loaded in the source. Therefore, changing the settings in the following steps is optional.

6. To offset the Carrier integration bandwidth relative to the Carrier LO used to generate the modulation signal, use the up/down arrows in the Carrier Offset Freq field or double-click in the field then enter the value using the displayed keypad.

7. To set the Carrier integration bandwidth for the distortion measurement, use the up/down arrows in the Carrier Integ BW field or double-click in the field then enter the value using the displayed keypad. The IBW is used to determine total signal power within a specified frequency span.

8. To adjust other measurement settings, click on the Measurement Details... button:
a. To set the frequency span window used for modeling the DUT’s gain and distortion, use the up/down arrows in the Distortion Measurement Correlation Aperture field or double-click in the field then enter the value using the displayed keypad. Checking Auto will automatically set Distortion Measurement Correlation Aperture to window size.

b. To select the IF filter anti-aliasing path, click on the ADC Anti-alias Filter pull down menu then select Auto, Wide, or Narrow. Auto will automatically set the ADC Filter setting based on the ADC Sampling Frequency. If the currently selected modulation waveform was created with Nyquist Rejection = OFF, then the VNA will measure the signal using the Narrow anti-alias filter in the receiver. Wide selects the ADC 38 MHz IF filter path. Narrow selects the ADC 11 MHz IF filter path. A warning message will appear if the Narrow IF filter path is selected and the Resolution Bandwidth is > 1 MHz.

c. To set the measurement filter to either None (default) or RRC (root-raised-cosine filter), click on the Modulation Filter pull down menu then make the selection. With RRC selected, Alpha sets the Alpha factor of the filter and Symbol Rate sets the Symbol Rate of the filter. If Auto is selected, the Symbol Rate from the file is used. If no Symbol Rate is indicated in the file, then the Symbol Rate will be approximated from the bandwidth of the signal.

d. To set the scaling factor applied to the EVM measurements. Enter a value between 0.1 and 1.0. The default is 1.0 using the up/down arrows in the EVM Normalization field.

e. To set the DUT noise figure, use the up/down arrows in the Nominal DUT NF field or double-click in the field then enter the value using the displayed keypad. This value is used by the EVM measurement. This setting adds noise to the measurement for more realistic results. The default is 0 dB. Setting the noise figure to a low value (-200 dB) will make EVM measurements without the effects of noise.

f. Click on the OK button.

9. Click on the Apply button to apply the setting changes made in this dialog.
10. Click on the **OK** button to close the dialog.

11. Ensure that the VNA Trigger is set to Continuous. Press **Trigger > Main > Continuous**.

12. The Distortion Table is displayed below the measurement area. Each column represents a measurement parameter. The measurement parameters shown in the Distortion Table below are the default parameters selected for an EVM measurement.

<table>
<thead>
<tr>
<th>Type</th>
<th>Carrier In1 dBm</th>
<th>Carrier Out2 dBm</th>
<th>Carrier Gain21 dB</th>
<th>Carrier IBW</th>
<th>EVM DistEq21 %</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVM</td>
<td>-20.07 dBm</td>
<td>-7.84 dBm</td>
<td>-13.00 dB</td>
<td>100.1 MHz</td>
<td>0.69 %</td>
</tr>
</tbody>
</table>

13. The measurement parameters are selected using the Distortion Table Setup dialog. To add or change parameters, press **Meas > Main > Distortion Table...** or right-click on the Distortion Table displayed below the measurement area then select **Edit Columns...** in the pop-up menu. The Distortion Table Setup dialog is displayed:

14. Select the **EVM** tab.
15. Check the desired measurement parameters then click on the OK button.

16. To view a trace displaying the equalized EVM of the DUT (non-linear contribution), perform the following:
   
a. Press **Meas > Main > Other...** then click on the "..." button. The **Measure** dialog is displayed:
b. Select the **Distortion** tab to display distortion traces:
c. Check **EVMDistEq21** then click on the **OK** button.

17. The following is an example of a typical trace and Distortion Table showing equalized distortion of the DUT:

![Graph of EVM vs Frequency](image)

**Un-equalized EVM of the DUT (Includes non-linear and linear distortion due to frequency dispersion)**

After setting up and performing an EVM measurement as described in the above procedure, perform the following procedure for a measurement that includes non-linear and linear distortion due to frequency dispersion.

1. Press **Meas > Main > Distortion Table**... or right-click on the Distortion Table displayed below the measurement area then select **Edit Columns**... in the pop-up menu.

2. In the Distortion Table Setup dialog, select the **EVM** tab.
3. Check the EVM DistUn21 % parameter then click on the OK button. The added parameter is displayed as a new column in the Distortion Table displayed below the measurement area.

4. To view a trace displaying the un-equalized EVM of the DUT, perform the following:

   a. Press Meas > Main > Other... then click on the "..." button. The Measure dialog is displayed:
b. Select the **Distortion** tab to display distortion traces:
c. In the **Distortion** tab, check **New trace**. If any parameters are currently checked, uncheck them.

d. Check **EVMDistUn21** then click on the **OK** button.

5. The following is an example of a typical trace and Distortion Table showing un-equalized distortion of the DUT:
Set Up a Band Power Measurement

Band Power measures the input carrier band power, output carrier band power, and band power gain of the DUT (magnitude and phase).

In this topic:

- Band Power Measurement Criteria
- Input/Output Band Power and Band Power Gain (magnitude and phase)

Band Power Measurement Criteria

The procedures in the list below must be performed prior to making Band Power measurements. For purposes of this example, the DUT used is an amplifier and the Modulation Type is Flat Tones.

- Required set up procedures:
  - Hardware Setup for Amplifiers
  - Create a Modulation Distortion Channel
  - Set Up a Sweep
  - Set Up the RF Path
  - Set Up the External Source
  - Set Up a Flat Tones Modulation Type

- Calibration procedures:
  - Phase Reference Wizard
  - S-Parameter Calibration
  - Receiver IF Cal
  - Source Modulation Calibration

Input/Output Band Power and Band Power Gain (magnitude and phase)

1. If the Modulation Distortion Setup dialog is not displayed, press Freq > SA Frequency > MOD Setup...

2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.

3. Select the Measure tab.
4. In the **Measurement Type** pull down menu, ensure that **Band Power** is selected (default).

5. Click on the **Autofill** button to automatically fill in the measurement settings for all bands from the currently active modulation file loaded in the source. Therefore, changing the settings in the following steps is optional.

6. To offset the Carrier integration bandwidth relative to the Carrier LO used to generate the modulation signal, use the up/down arrows in the **Carrier Offset Freq** field or double-click in the field then enter the value using the displayed keypad.

7. To set the Carrier integration bandwidth for the distortion measurement, use the up/down arrows in the **Carrier Integ BW** field or double-click in the field then enter the value using the displayed keypad. The IBW is used to determine total signal power within a specified frequency span.

8. To adjust other measurement settings, click on the **Measurement Details...** button:
To set the frequency span window used for modeling the DUT’s gain and distortion, use the up/down arrows in the Distortion Measurement Correlation Aperture field or double-click in the field then enter the value using the displayed keypad. Checking Auto will automatically set Distortion Measurement Correlation Aperture to window size.

To select the IF filter anti-aliasing path, click on the ADC Anti-alias Filter pull down menu then select Auto, Wide, or Narrow. Auto will automatically set the ADC Filter setting based on the ADC Sampling Frequency. If the currently selected modulation waveform was created with Nyquist Rejection = OFF, then the VNA will measure the signal using the Narrow anti-alias filter in the receiver. Wide selects the ADC 38 MHz IF filter path. Narrow selects the ADC 11 MHz IF filter path. A warning message will appear if the Narrow IF filter path is selected and the Resolution Bandwidth is > 1 MHz.

To set the measurement filter to either None (default) or RRC (root-raised-cosine filter), click on the Modulation Filter pull down menu then make the selection. With RRC selected, Alpha sets the Alpha factor of the filter and Symbol Rate sets the Symbol Rate of the filter. If Auto is selected, the Symbol Rate from the file is used. If no Symbol Rate is indicated in the file, then the Symbol Rate will be approximated from the bandwidth of the signal.

Click on the OK button.

9. Click on the Apply button to apply the setting changes made in this dialog.

10. Click on the OK button to close the dialog.

11. Ensure that the VNA Trigger is set to Continuous. Press Trigger > Main > Continuous.

12. The Distortion Table is displayed below the measurement area. Each column represents a measurement parameter. The measurement parameters shown in the Distortion Table below are the default parameters selected for a Band Power measurement.
13. The measurement parameters are selected using the Distortion Table Setup dialog. To add or change parameters, press **Meas > Main > Distortion Table...** or right-click on the Distortion Table displayed below the measurement area then select **Edit Columns...** in the pop-up menu. The **Distortion Table Setup** dialog is displayed:

![Distortion Table Setup dialog](image)

14. Check the desired measurement parameters then click on the **OK** button.

15. To view a trace displaying the Input/Output Band Power and Band Power Gain, perform the following:

   a. Press **Meas > Main > Other...** then click on the "..." button. The **Measure** dialog is displayed:
b. Select the **Distortion** tab to display distortion traces:
c. Check **CarrIn1** to measure input Band Power then click on the **Apply** button.

d. In the **Distortion** tab, check **New trace**. If any parameters are currently checked, uncheck them.

e. Check **CarrOut2** to measure the output Band Power then click on the **Apply** button.

f. In the **Distortion** tab, check **New trace**. If any parameters are currently checked, uncheck them.

g. Check **CarrGain21** to measure the Band Power gain then click on the **OK** button.

h. If necessary, press **Scale** > **Main** > **Scale Coupling** ..., select **Window** as the **Coupling Method**, then click **OK**. This re-scales all traces to the same scale.

i. Click on the **Autoscale All** softkey.

16. The following is an example of a typical trace and Distortion Table showing input and output Band Power and Band Power Gain:
Set Up a NPR Measurement

NPR Notch is a Noise Power Ratio measurement. The notch is created where no signals are present. With the stimulus applied to the DUT, the ratio of the noise power of the carrier to the noise power in the notch is measured.

In this topic:

- NPR Measurement Criteria
- Input/Output NPR and NPR Contribution of the DUT

NPR Measurement Criteria

The procedures in the list below must be performed prior to making NPR measurements. For purposes of this example, the DUT used is an amplifier and the Modulation Type is NPR Notch.

- Required set up procedures:
  - Hardware Setup for Amplifiers
  - Create a Modulation Distortion Channel
  - Set Up a Sweep
  - Set Up the RF Path
  - Set Up the External Source
  - Set Up a NPR Notch Modulation Type

- Calibration procedures:
  - Phase Reference Wizard
  - S-Parameter Calibration
  - Receiver IF Cal
  - Source Modulation Calibration

Input/Output NPR and NPR Contribution of the DUT

1. If the Modulation Distortion Setup dialog is not displayed, press Freq > SA Frequency > MOD Setup...

2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.

3. Select the Measure tab.
4. In the **Measurement Type** pull down menu, select **NPR**.
5. Click on the **Autofill** button to automatically fill in the measurement settings for all bands from the currently active modulation file loaded in the source. Therefore, changing the settings in the following steps is optional.

6. To offset the Carrier integration bandwidth relative to the Carrier LO used to generate the modulation signal, use the up/down arrows in the **Carrier Offset Freq** field or double-click in the field then enter the value using the displayed keypad.

7. To set the Carrier integration bandwidth for the distortion measurement, use the up/down arrows in the **Carrier Integ BW** field or double-click in the field then enter the value using the displayed keypad. The IBW is used to determine total signal power within a specified frequency span.

8. To offset the Notch center relative to the carrier LO used to generate the modulation signal, use the up/down arrows in the **Notch Offset Freq** field or double-click in the field then enter the value using the displayed keypad.

9. To set the integration bandwidth of the NPR notch measurement, use the up/down arrows in the **Notch Integ BW** field or double-click in the field then enter the value using the displayed keypad.

10. To adjust other measurement settings, click on the **Measurement Details...** button:

![Measurement Details](image)

    a. To set the frequency span window used for modeling the DUT’s gain and distortion, use the up/down arrows in the **Distortion Measurement Correlation Aperture** field or double-click in the field then enter the value using the displayed keypad. Checking **Auto** will automatically set **Distortion Measurement Correlation Aperture** to window size.

    b. To select the IF filter anti-aliasing path, click on the **ADC Anti-alias Filter** pull down menu then select **Auto**, **Wide**, or **Narrow**. **Auto** will automatically set the ADC Filter setting based on the ADC Sampling Frequency. If the currently selected modulation waveform was created with Nyquist Rejection = OFF, then the VNA will measure the signal using the Narrow anti-alias filter in the receiver. **Wide** selects the ADC 38 MHz IF filter path. **Narrow** selects the ADC 11 MHz IF filter path. A warning
message will appear if the Narrow IF filter path is selected and the Resolution Bandwidth is > 1 MHz.

c. To set the measurement filter to either None (default) or RRC (root-raised-cosine filter), click on the Modulation Filter pull down menu then make the selection. With RRC selected, Alpha sets the Alpha factor of the filter and Symbol Rate sets the Symbol Rate of the filter. If Auto is selected, the Symbol Rate from the file is used. If no Symbol Rate is indicated in the file, then the Symbol Rate will be approximated from the bandwidth of the signal.

d. Click on the OK button.

11. Click on the Apply button to apply the setting changes made in this dialog.

12. Click on the OK button to close the dialog.

13. Ensure that the VNA Trigger is set to Continuous. Press Trigger > Main > Continuous .

14. The Distortion Table is displayed below the measurement area. Each column represents a measurement parameter. The measurement parameters shown in the Distortion Table below are the default parameters selected for an NPR measurement. In this case, only the output NPR is selected so the input NPR will be added in the following steps.

<table>
<thead>
<tr>
<th>Type</th>
<th>Carrier In1 dBm</th>
<th>Carrier Out2 dBm</th>
<th>Carrier Gain21 dB</th>
<th>Carrier IBW</th>
<th>NPR Out2 dBC</th>
</tr>
</thead>
<tbody>
<tr>
<td>NPR</td>
<td>-19.15 dBm</td>
<td>-7.84 dBm</td>
<td>-13.00 dB</td>
<td>90.00 MHz</td>
<td>-42.07 dBc</td>
</tr>
</tbody>
</table>

15. The measurement parameters are selected using the Distortion Table Setup dialog. To add or change parameters, press Meas > Main > Distortion Table... or right-click on the Distortion Table displayed below the measurement area then select Edit Columns... in the pop-up menu. The Distortion Table Setup dialog is displayed:
16. Select the **NPR** tab.
17. Check the **NPR In1 dBc** (input NPR) and **NPR Dist21 dBc** (NPR contribution by DUT) measurement parameters then click on the **OK** button.

18. To view traces displaying the Input/Output NPR and NPR contribution by DUT, perform the following:

   a. Press **Meas > Main > Other...** then click on the "..." button. The **Measure** dialog is displayed:
b. Select the **Distortion** tab to display distortion traces:
c. Check NPRIn1 to measure input NPR then click on the Apply button.

d. In the Distortion tab, check New trace. If any parameters are currently checked, uncheck them.

e. Check NPROut2 to measure the output NPR then click on the Apply button.

f. In the Distortion tab, check New trace. If any parameters are currently checked, uncheck them.

g. Check NPRDist21 to measure the NPR contribution by the DUT then click on the OK button.

h. If necessary, press Scale > Main > Scale Coupling ..., select Window as the Coupling Method, then click OK. This re-scales all traces to the same scale.

i. Click on the Autoscale All softkey.

19. The following is an example of a typical trace and Distortion Table showing input and output NPR and NPR contribution of the DUT:
Set Up a Multi-Band Measurement

The Multi-Band measurement allows multiple measurement types with corresponding measurement data to be displayed in a single table.

In this topic:

- Multi-Band Measurement Criteria
- Multi-Band Measurement Setup

Multi-Band Measurement Criteria

The procedures in the list below must be performed prior to making Multi-Band measurements. For purposes of this example, the DUT used is an amplifier and the Modulation Type is Flat Tones.

- Required set up procedures:
  - Hardware Setup for Amplifiers
  - Create a Modulation Distortion Channel
  - Set Up a Sweep
  - Set Up the RF Path
  - Set Up the External Source
  - Set Up a Flat Tones Modulation Type

- Calibration procedures:
  - Phase Reference Wizard
  - S-Parameter Calibration
  - Receiver IF Cal
  - Source Modulation Calibration

Multi-Band Measurement Setup

1. If the Modulation Distortion Setup dialog is not displayed, press Freq > SA Frequency > MOD Setup...

2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.

3. Select the Measure tab.
4. In the **Measurement Type** pull down menu, select **Multi-Band**.
5. Click on the **Edit Table** pull down menu then select **Append Band**.

6. In the **MeasType** column for the new entry, select **ACP**.

7. Click on the **Edit Table** pull down menu then select **Append Band**.

8. In the **MeasType** column for the new entry, select **EVM**.

9. Click on the **Edit Table** pull down menu then select **Autofill Current Table from Mod File**. Measurement settings from the currently active modulation file loaded in the source are used for all measurement types in the table.

10. To change the band name, right-click in the **Band Name** field to display a keyboard for editing the name.

11. Type in the band name then click on **Enter**.

12. Click on the **Apply** button to apply the changes. The Multi-Band table is displayed below the measurement area with the default measurement parameters.

13. Click on the **OK** button to close the dialog.

14. Additional measurement parameters can be selected for any measurement type using the Distortion Table Setup dialog. Press **Meas > Main > Distortion Table** or right-click on the Distortion Table displayed below the measurement area then select **Edit Columns**... in the pop-up menu. The **Distortion Table Setup** dialog is displayed:
15. Select the measurement type tab then add the desired measurement parameters.

16. Click on the **OK** button to close the dialog.

17. Ensure that the VNA Trigger is set to Continuous. Press **Trigger > Main > Continuous**.

18. The following shows a Multi-Band measurement:

<table>
<thead>
<tr>
<th>Band</th>
<th>Type</th>
<th>Carrier In1 dBm</th>
<th>Carrier Out2 dBm</th>
<th>Carrier Gain21 dB</th>
<th>Carrier IBW</th>
<th>EVM DistEq21 %</th>

<td>12.94 dB</td>
<td>100.1 MHz</td>
<td>-44.70 dBC</td>
<td>-53.62 dBC</td>
<td>-44.87 dBC</td>
<td>-53.72 dBC</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** NPR was not measured because it requires a NPR Notch modulation type instead of the Flat Tones modulation type used here to measure ACP, EVM, and Band Power.
Set Up a Power Sweep Measurement

A Power Sweep measurement can be set up to sweep power within a specified power range and specified number of powers. A trace can be set up to display input power on the X axis with the EVM measurement on the Y axis. This displays a "bathtub" type curve due to noise at low power levels and distortion at high power levels.

1. If the Modulation Distortion Setup dialog is not displayed, press Freq > SA Frequency > MOD Setup...

2. The Sweep, RF Path, Modulate, or Measure tab functions can now be selected.

3. Select the Sweep tab.

4. Click on the Sweep Type pull down menu then select Power.

5. Set the Carrier Frequency by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This is dependent upon the frequency of the DUT.

6. Set the SA Center by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This sets the Spectrum Analyzer display center.

7. Set the SA Span by either using the up/down arrows or by double-clicking in the data entry field and entering
the frequency using the displayed keypad. This sets the Spectrum Analyzer (SA) display span. The following graphic shows the SA display set to the same center frequency as the Carrier and covering a span that includes the integrated bandwidth settings of ACPLo + Carrier + ACPUp.

8. Set the Noise BW by either using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. Noise BW is equal to the Resolution BW divided by the Vector Average factor.

9. Click on the Sweep Details... button to set the following:

- **Force RF Power OFF at the End of Sweep - System Preference** - If enabled, RF power is turned off at the end of a sweep.

- **Delay Before Start of Sweep** - Same as Sweep Delay in a standard channel.

- **Delay Before Distortion Measurement** - Adds delay after the linear S-parameter sweep and before the distortion measurement to allow the RF source to settle.

- **Enable S-Param Sweep** - Enables S-parameters to be measured at the low linear power level. If disabled (default), curve fitting (smoothing) is used instead of the S-parameter sweep. Curve fitting can be adjusted by varying the window aperture using the Distortion Measurement Correlation Aperture setting in the Measurement Details dialog.

- **S-Param Source** - Selects source and signal used to measure S-parameters.

- **External Vector - Chirp** - Selects a chirp signal from the external signal generator for measuring S-parameters.

- **S-Param Power** - Sets the power level used at the DUT input to measure the DUT gain when operating in its linear region. The linear gain is used to calculate distortion.
- **S-Param Freq Step** - Frequency step size setting used when measuring S-parameters.
- **S-Param IFBW** - Bandwidth setting when measuring S-parameters.
- **Re-use Previous S-Parameter Measurements If Available** - If disabled, S-parameters will be measured at the low linear power level. If enabled and compatible measurements exist from a previous sweep, those measurements will be used and a Linear S-parameter sweep will not be performed. If enabled and compatible measurements are not available, then a Linear S-parameter sweep will be performed.

19. Click on the **Power Sweep...** button to set up the **Power Sweep** dialog as follows:

![Power Sweep Dialog](image)

   a. Set **Start Power At** to -20 dBm.
   b. Set **Stop Power At** to 0 dBm.
   c. Set **Number of Powers** to 21.
   d. Set **Noise BW** to 520.833 Hz.
   e. Click **OK**.

20. Select the **Set Power At** pull down to set the power at the **DUT In**.

21. To set up a power supply, click on the **DC Sources...** button which accesses the standard dialog for controlling power supplies. Learn more.
22. Click on the **Apply** button to apply the setting changes made in this dialog.

23. Set up an EVM measurement as described in Set Up an EVM Measurement.

24. To view a trace displaying the equalized EVM of the DUT (non-linear contribution), perform the following:

   a. Press **Meas > Main > Other...** then click on the "..." button. The **Measure** dialog is displayed:

   ![Measure dialog](image1.png)

   b. Select the **Distortion** tab to display distortion traces:

   ![Distortion tab](image2.png)
c. Check **EVMDistEq21** then click on the **OK** button. This trace measures the EVM equalized distortion added by DUT (non-linear contribution).

25. Select **Sweep** > **Main** > **X-axis Type**... and ensure that the **X-axis Type** is set to **Power In**.

26. Click on the **OK** button.

27. The following is an example of a typical "Bathtub" trace and Distortion Table showing power sweep values:
<table>
<thead>
<tr>
<th>Power (dBm)</th>
<th>Type</th>

Noise Figure Hardware and Software Options Explained

See Also: PNA-X Noise Figure Options (VNA Configuration Guide) - Internet connection required

- **029** - (PNA-X ONLY) Includes low-noise receivers and noise tuner bypass switch to enable noise figure measurements to 50 GHz. Also includes Opt 028 capability.

- **028** - Uses VNA receivers to measure noise figure. A noise source is NOT used during calibration. Any two ports can be used. Use with DUTs that have sufficiently high gain and noise figure. Additional filtering may be necessary. Learn more.

- **S93027B** - (PNA-X ONLY) Allows PNA-X models with Opt 029 to use mechanical noise tuners. Learn more.

- **S9x029A/B** - Noise figure measurement application. A Noise tuner and noise figure measurement of frequency translating devices are not supported.

- **H29 (obsolete)** - Noise Figure on N5244A (43.5 GHz PNA-X model) and N5245A (50 GHz PNA-X model). Includes both:
  
  - Opt 029 hardware from the N5242A (noise measurements to 26.5 GHz)
  

  **Note:** Option H29 does not include an internal noise tuner.

50 GHz Noise Figure Receivers

Beginning in October 2012, Option 029 (low-noise receivers) is available in the N5244B (43 GHz), N5245B (50 GHz), and N5247B (67 GHz) models.
• The low-noise receiver and the noise receiver path switch is added between the port 2 CPLR THRU jumper connector and the port 2 bias tee. See Option 029 block diagram below. When it is configured with a multiport test set (i.e. U3024AH10), the low-noise receiver cannot be used with test ports on the test set with standard multiport test set jumper connections. See modified test set connections to use 50 GHz low-noise receiver with multiport test set.

• These models (with option 029) include a built-in (internal) Noise Tuner which can be selected at the beginning of the Noise Figure Calibration. The Noise Tuner switch is managed differently than in 26.5 GHz models. Learn more.

• When used with the N5247A, Noise Figure measurements between 50 GHz and 67 GHz are possible using the standard receivers (Opt 028) and a 67 GHz Power Sensor. See Opt 028 Measurement tips.

• See limitations of the 50 GHz Noise Source.

• See Using Opt. 029 (low-noise receiver) with External Test Set

Noise Figure Application Features

• Cold noise method includes correction for imperfect system source match for highly accurate noise figure measurements.

• With Opt 029/S93029A/B you can measure devices with noise figure values ranging from about 0 to 50 dB and devices with GAIN ranging from about -40 to +60 dB. Learn more.

• With Opt 028/S93029A/B you can also measure noise figure using standard VNA receivers. Learn more.

• Measure noise figure of frequency translating devices. Learn more.

• During calibration, ENR values are interpolated for frequencies between the supplied data points.

Noise Figure Application Requirements

• Noise Tuner - Required for vector noise figure measurements. Not required for scalar noise figure.

  • ONLY the N4690 Series ECal modules are supported. The N4691B m-f is recommended.

  • Opt 029 provides an additional cable and adapter to connect the ECal module to the front-panel connectors. Learn more.

  • A built-in Noise Tuner is provided with the 50 GHz noise receiver models. Learn more.

• Power Meter - Required when calibrating NFX (Noise Figure on Converters).

• Recommended: An accurate thermometer. Learn more.
**Noise Source**

A Noise Source is NOT required to calibrate the Opt 029 Noise Receivers. Instead, the Noise Receivers can be calibrated using a calibrated VNA source. [Learn more.](#)

When using a Noise Source, the following requirements apply:

- The 346C Noise Source (recommended) produces ENR values to 26.5 GHz.
- The 346B Noise Source can be used up to 18 GHz.
- The 346A Noise Source can also be used up to 18 GHz, but requires more averaging for calibration.
- The 346C K01 (50 GHz) Noise Source typically has about 6 dB of ENR at 50 GHz which may NOT yield an adequate calibration, depending on how many noise averages are used. An alternative approach calibrates the noise receivers using a power sensor-based method. Select [Use Power Meter](#) for the noise figure calibration. [Learn more.](#)
- The U1831C Noise Source can be used up to 26.5 GHz.
- The U1832(A/B/C/D) and U1833(A/B/C/D) Noise Sources can be used.
  - A: 26.5GHz, B: 50GHz, C: 50GHz D: 55GHz
  - U1832X: Low ENR models
  - U1833X: High ENR models
- An adapter may be necessary to connect the Noise Source to the VNA port 2 reference plane during [calibration](#). Cal Kit (or second ECal module) with same connector type and gender as DUT connectors.

**Limitations with the Noise Figure Application**

The following features are NOT supported in a noise figure channel:

- [FCA or Frequency Offset](#)
- [Analog sweep](#). All frequency sweeps are STEPPED.
- Independent IFBW, Power Levels, or Sweep Time in a segment table is NOT supported.
- [External Test Set Control](Opt S93551A/B)
- Receiver calibration.
- Enhanced Response Cal
- ECAL User Characterization.
- Some Fixturing Features
- Auto Port Extensions
- Auto Formatted Citifile data.
- External DC Devices

- Pulsed noise figure measurements are supported with the following limitations:
  - Minimum 300 microsecond pulse width using 24 MHz noise bandwidth
  - Narrower noise bandwidths cause larger minimum pulse widths
  - A drop-out may occur at start of sweep and at 3 GHz. This is corrected by a 1 ms pulse width at 24 MHz Noise BW.

- Option 205 or Option 425

### Noise Concepts

The following conceptual information is a short summary taken from the Keysight Noise Figure App Note 57-1.

All electronic circuits have some degree of random noise. The most common form is thermal noise, which increases as the temperature of the circuit increases.

The signal-to-noise (S/N) ratio of components in a communications system is a very important parameter. To improve the S/N ratio, it is usually easier and more cost-effective to reduce noise than to increase signal power. In order to reduce noise, an accurate method to measure noise is required.

### Noise Figure

Noise Figure is the degradation in the signal-to-noise ratio as a signal passes through a device. For example, in the following images:
(a) At the INPUT of the DUT:
The noise floor is -100 dBm, the signal is at -60 dBm, 40 dB above the noise floor.

(b) At the OUTPUT of the same DUT:
The gain has boosted the signal AND the noise floor by 20 dB.
The DUT then added 10 dB of its own noise.
The output signal is now only 30 dB above the noise floor.
Since the degradation in signal-to-noise ratio is 10 dB, the DUT has a 10 dB noise figure.

For consistency, noise measurements are calculated as if using a 1 Hz bandwidth, although measurements are almost always made at higher bandwidths.

The following formula shows the lowest possible noise power in dBm at 290°K (room temperature). The only way to measure noise lower than this is to make the measurement at a lower temperature.

- \[ P = 10 \log(4.0 \times 10^{-21} \, \text{watts} / 0.001 \, \text{watt}) \]
- \[ P = -174 \, \text{dBm} / \text{Hz} \]

**How the Noise Figure Application Works**

The goal of the noise figure application is to accurately measure the noise that is generated by the DUT. This may be done using special low-noise receivers or using the standard VNA receivers depending on whether the VNA has Options 029 or 02. Learn more.
The standard receivers are always calibrated using a power meter and a measurement of the receivers effective noise bandwidth. The low-noise receivers can be calibrated using either a characterized noise source or using the same process as a standard VNA source. Learn more about the noise calibration process.

Some noise measurement error is caused by a poor source match presented to the DUT input. Therefore, during every measurement, the noise figure application uses an ECal module to present at least four different impedances at the input of the DUT. This "Noise Tuner" is connected to the VNA port 1 front-panel loops that are in the VNA internal source path (see block diagram below). From the measurements at various impedance states, the VNA calculates the noise out of the DUT as though the VNA were exactly 50 ohms. No assumptions are made regarding the input impedance of the DUT.

Here is how a vector noise figure measurement is made using Option 029. The sweep numbers are annotated on the VNA display as they occur.

1. With the noise tuner in the THRU state, S-parameter measurements are made to accurately characterize the gain of the DUT. This requires sweeps in both forward and reverse directions. (sweep #1 and #2).

2. The noise measurements are performed next. VNA source power is turned OFF and the noise tuner is switched to the first impedance state.

3. At each frequency, the noise receiver samples a large number of readings in order to attain one valid measurement. If Noise Averaging is selected, the specified number of measurements are made and averaged together to obtain one noise measurement. This continues for all frequencies (sweep #3).

4. The next noise tuner impedance state is switched IN and the noise measurements in step 3 are repeated. This occurs until measurements are made at all impedance states. At least four impedance states must be used. (sweeps #4, #5, #6+)

5. Calibration error terms are applied and calculations made to simulate the measurement with a perfect 50 ohm input impedance. The sweep result is plotted on the VNA display.

6. The VNA begins sweeping again with step 1.

**Scalar Noise Figure Measurements**

As described above, the noise tuner is switched to at least four different impedance states before a sweep is plotted. These sweeps are NOT made in a scalar noise figure measurement, resulting in much faster measurements. Of course, a scalar noise figure measurement is NOT as accurate as a vector noise figure measurement because scalar noise figure measurements assumes that all impedances are 50 ohms. Measurement accuracy can be improved by adding an attenuator as close to the DUT input as possible. This improves the effective system source match. The effect of the attenuator loss is removed during the calibration process.

With scalar noise figure, it is not necessary to connect the noise tuner. If a noise tuner remains connected, it is switched to the THRU state for scalar noise figure measurements. This results in a small
amount of loss which slightly degrades measurement accuracy. To increase measurement accuracy, manually switch the noise tuner switch to the INTERNAL position. Learn how.

Select Scalar Noise at the first page of a Noise Figure calibration.

50 GHz Noise Figure Components are shaded yellow

- At test port 1 front-panel loops, a noise tuner bypass switch connects the noise tuner (ECal module) in series with Source1 providing several different input impedances.

- At test port 2, a switch and coupler to route RF from the DUT output to two noise receivers. The appropriate receiver is automatically switched as required for the frequency being measured.
26.5 GHz Noise Figure Components are shaded yellow

- At test port 1 front-panel loops, a **noise tuner bypass switch** connects the noise tuner (ECal module) in series with Source 1 providing several different input impedances. Learn more about managing the Noise Tuner switch.

- At test port 2, a **switch** and **coupler** to route RF from the DUT output to **two noise receivers**. The appropriate receiver is automatically switched as required for the frequency being measured.
50 GHz Noise Figure Components are shaded yellow

- At test port 1, a **noise tuner bypass switch** connects the built-in noise tuner in series with Source1 providing several different input impedances. Learn more about managing the Noise Tuner switch.

- At test port 2, a **switch** routes RF from the DUT output to **two noise receivers**. The appropriate receiver is automatically switched as required for the frequency being measured. For using the noise receiver with an external test set, see 50 GHz Noise Figure with Opt. 029 and External Test Set.

**Noise Figure Option S93027B**

Option S93027B allows a PNA-X with a low-noise receiver to use specialized mechanical tuners on the input port. These tuners are designed to have a large number of impedance states that are broadly distributed on a Smith chart. There are two situations in which a mechanical tuner is advantageous:

1. When measuring noise figure at low frequencies. While Ecals are good general-purpose tuners, they tend to have a suboptimal spread of impedance states at low frequencies.
2. When measuring NF of a device that is poorly matched. Ecal modules are well suited to measure the noise figure of devices with a match near 50 ohms, but do not perform as well with devices that have match far from 50 ohms.

Mechanical tuners also improve the quality of the Noise Parameter measurements NFmin, GammaOpt, and Rho.

The following tuners are supported by Option S93027B. All are manufactured by Maury Microwave.

</tbody>
</table>

To use a tuner supported by Option S93027B, follow this procedure:

1. Download driver files for the tuner at the Web address shown below:

2. Run the driver installation program.

3. Power up the tuner and connect it to the PNA via a USB cable.

4. The tuner should now be available for use. To verify this, start the PNA application and create a Noise Figure or Noise Figure Converters channel. Start the Calibration Wizard, and expand the selections for the Noise Tuner combo box. The attached tuner should appear in the displayed list. In the example below, a Maury Microwave MT982BL01 tuner was used.
5. Once the tuner has been recognized, it should be inserted into the signal path between port 1 and the DUT input. To increase measurement accuracy, it is best to have the tuner as close to the port 2 calibration plane as possible. This ensures that the spread of tuner impedances is as large as possible.

**Calibrating with a Mechanical Tuner**

No special steps are required to use a mechanical tuner for noise figure calibration. After verifying that the tuner is recognized by the PNA, simply perform a noise figure calibration in the usual way. The PNA firmware will measure all impedance states of the tuner during calibration. When the calibration is complete, the number of states used in vector NF correction can be set in the Noise Figure Setup dialog. In the example below, 15 states have been chosen, but up to 21 states are available.

**Caveats when using a Mechanical Tuner**

Mechanical tuners offer distinct advantages, but there are caveats to keep in mind:
Mechanical tuners are slow. They take more time to move from one impedance state to another than Ecal modules do. This increases the amount of time required for corrected NF measurements.

Because of the increased measurement time, interference can be more of an issue. Any external signals that can interfere with a noise figure measurement, such as cell phone traffic, have more opportunity to intrude. This is important to keep in mind if you are making lengthy measurements in an unshielded environment.

The number of sweeps taken during a vector corrected measurement is usually equal to the number of impedance states, plus two (for the forward and reverse S-parameter measurements). If a mechanical tuner is used, the number of sweeps may be about twice as large. This is because (depending upon frequency range) the tuner may need to take two sweeps per impedance state, one for low band, the other for high band.

If a Noise sweep is aborted for any reason, such as a change in stimulus conditions, the dialog below may appear. This is because the PNA is waiting for the tuner to complete an operation. The dialog should disappear after the pending operation is complete.

The Noise Tuner Switch while making S-parameter measurements

Because of the built-in Noise Tuner in the Option 029 50 GHz noise figure models, the Noise Tuner switch is managed differently than the 26.5 GHz noise figure models.

26.5 GHz Models

The default setting for the port 1 noise tuner switch is "External" as shown in the above diagram. This setting provides incident power through the front panel loops and the Noise Tuner when connected. When connected, the Noise Tuner may NOT be in the THRU state, which is necessary for accurate S-parameter measurements.

The switch is changed in any of the following ways:

- Set the switch to INTERNAL for the S-parameter channel using the path configuration dialog.
- Set the switch to INTERNAL for the S-parameter channel using the following commands:
  - SCPI - SENS:PATH:CONF:ELEM:STAT "Port1NoiseTuner", "Internal"
- COM - PathConfiguration.Element("Port1NoiseTuner").Value = "Internal"

- Set the switch default to INTERNAL using a preference setting.

- Set the Noise Tuner (ECal module) to the THRU state using SCPI: CONT:ECAL:MOD:PATH:STATE.

**Important Note:** On the 26.5 GHz Opt 029 models, once you set this switch to "Internal", you must set it back to "External" to make noise figure measurements. The switch is NOT automatically set to "Internal" during a noise figure measurement.

**50 GHz Models**

The switch for the built-in tuner (Opt. 029) is set to "Internal" (Tuner) ONLY when making vector noise figure measurements. Otherwise, it is set to "Bypass" (the tuner). Therefore, you should NOT need to make switch settings. However, the switch can be changed in any of the following ways:

- Using the path configuration dialog.

- Using the following commands:
  
  - SCPI - SENS:PATH:CONF:ELEM:STAT "Port1NoiseTuner", "Bypass" (or "Internal")
  
  - COM - PathConfiguration.Element("Port1NoiseTuner").Value = "Bypass" (or "Internal")

- Manage the built-in Noise Tuner impedance states using the SCPI and COM commands and Element / Value settings.

**Using the Noise Figure Application**

Use the following general procedure to make noise figure measurements:

1. Connect Tuner and Noise Source.

2. Create a Noise Figure Measurement.

3. Make Noise Figure Settings.

4. For Opt 029 and H29, copy your Noise Source ENR file to the VNA "C:\Program Files(x86)\Keysight\Network Analyzer\Noise folder"

5. Perform Calibration

6. Connect the DUT. Learn more about DUT input and output ports.

7. Measure Noise Figure.
8. Optional Click File, then Save to save noise figure data. Learn more.

**Connect Noise Tuner and Noise Source**

- Connect the noise source to the 28V connector on the VNA rear panel. **NOT required for Opt 028.** The Noise Source is turned ON and OFF automatically as needed during a calibration. Connect the noise source to Port 2 reference plane when prompted during calibration.

- Connect the noise tuner (ECal module). See Noise Tuner requirements.

  a. On the VNA front panel, remove the Port 1 jumper cable SOURCE OUT / CPLR THRU. Opt 028 allows noise figure measurements using any two VNA ports.

  b. Connect the noise tuner to the front-panel jumpers for the source (DUT input) port.

See the VNA Configuration Guide for recommended ECal modules, cables, and adapters.

**Create a Noise Figure Measurement**

1. On the VNA front panel, press Meas > S-Param > Meas Class....

2. Select Noise Figure Cold Source, then either:

   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.

3. A noise figure measurement is displayed. The following shows how to select or change displayed parameters.

**Noise Parameters**
Several noise parameters, as well as standard parameters, can be measured in the same Noise channel.

### How to add Noise Parameters

1. Create a Noise Figure channel.
2. Then do the following:

**Using Hardkey/SoftTab/Softkey**

1. Press **Trace > Trace N > Trace N**.
2. Press **Trace > Trace Setup > Measure...**

**Using a mouse**

1. Click **Instrument**
2. Select **Trace**
3. Select **Add Trace**
4. Click **Instrument**
5. Select **Trace**
6. Select **Measure...**

### How to CHANGE Noise Parameters

1. Create a Noise Figure channel.
2. Select the parameter to change.
3. Then do the following:

1. Select a trace by pressing **Trace > Trace N > Trace N**.
2. Press **Trace > Trace Setup > Measure...**
3. Select a parameter.

### Programming Commands

#### Noise Measurements that are offered

The following three categories of noise measurements can be made with the VNA:

1. **Noise Figure** is the amount of noise that the DUT is adding in a 50 ohm test setup. This is explained in detail in Noise Concepts.

2. **Noise Power Parameters** show the amount of noise coming out of the DUT in a 50 ohm test setup. With gain
measurements of the DUT, these noise power parameters are used to calculate noise figure.

3. **Noise Parameters** are models of the noise that is generated in a DUT, similar to how S-parameters model how RF flows through a DUT.

- **Noise Figure (NF)** - Explained in Noise concepts.
- **Excess Noise Ratio** - Select when measuring the noise source. Compare with the ENR table to validate accuracy of the system. ENR is calculated as:

\[
\text{ENR (in dB) = } 10 \log_{10} \left( \frac{T_{\text{hot}} - T_{\text{cold}}}{T_0} \right), \text{ where } T_0 = 290K.
\]

Learn more about the ENR table and Noise Source. Learn more about Noise Source ENR measurements.

- **T-Effective** - The effective temperature, in Kelvin, of the measured noise level. For example:

\[
290^\circ K = -174 \text{ dBm/Hz}.
\]

Available Gain \( G_a \) is a function of \( S_{11}, S_{22}, \) and \( \Gamma_s \)

**Noise Power Parameters**

The Noise Power parameters below are offered in the following two formats:

- **Available Noise Power**  The calculated power that is based on an ideal impedance match at the output of the DUT. These parameters have always been offered in the VNA noise figure App.

- **Incident Noise Power**  An 'I' is appended to the end of the Available Noise Power parameter. The calculated power into a perfect 50 ohm noise receiver, regardless of the output impedance of the DUT.

- **SYSNP / SYSNPD** - System Noise Power Density: Total noise power available at the ADC, including the noise contributed by both the DUT and the internal noise receiver. This is generally expressed as an
absolute power measurement in dBm, but can also be expressed in Watts or Kelvin.

\[ \text{dBm} = 10 \log_{10}(k \times T \times B \times 1000) \]

where:
- \( k \) = Boltzmann's constant
- \( T \) = the measured noise temperature
- \( B \) = bandwidth
- \( 1000 \) = conversion from milliwatts

- **SYSRNP / SYSRNPI** - System Relative Noise Power: The noise temperature of the combined DUT and receiver relative to 290 Kelvin. This is generally reported as a ratio in dB. Therefore a perfectly quiet device would render a trace at 0 dB.

\[ \text{dB} = 10 \log_{10}(T/290) \]

- **DUTNPD / DUTNPDI** - DUT Noise Power Density: When correction is ON, this trace exhibits the available noise power, best described as the maximum power available from the DUT where the impedance of the noise port is equal to the output match of the DUT. To be more precise, this occurs when the noise port match is equal to the conjugate of the output match of the DUT. The noise power contributed by the receiver is removed.

When correction is OFF, the trace exhibits what is more accurately described as delivered power. Delivered power is the power actually seen by the ADC. Any mismatch between the receiver and the DUT is ignored. The noise power contributed by the receiver is removed.

This measurement is generally expressed in dBm, normalized to a 1 Hz bandwidth. For convenience, marker and trace readout shows **dBm**.

You could display the power in a different bandwidth using Equation Editor.

\[ \text{dBm/Hz} = 10 \log_{10}( (\text{DUT Temperature} - \text{Receiver Temperature}) \times B \times 1000) \]

where:
- \( B \) = bandwidth
- \( 1000 \) = conversion from milliwatts

- **DUTRNP / DUTRNPI** - DUT Relative Noise Power: This measurement is rendered as a ratio of the DUT temperature to 290 Kelvin. It is generally expressed in dB. The same comments apply with respect to available versus delivered power as described above for DUTNPD.

\[ \text{dB} = 10 \log_{10} (\text{DUT Temperature} - \text{Receiver Temperature}) \]
Noise Model, Noise Parameters, and the Noise Correlation Matrix

Noise Parameters are models of the noise that is generated in a DUT, similar to how S-parameters model how RF flows through a DUT.

Noise Model

The noise wave model of any linear 2-port network may be represented by the following image:

This shows a noiseless 2-port network with noise waves ($a_{n1}$ and $b_{n1}$) added to the input terminals. The $a_1$, $a_2$, $b_1$, and $b_2$ are standard S-parameter waves.

The noise correlation matrix relates to the noise waves as follows:

\[
C_\mathbf{c} = \begin{bmatrix}
|a_{n1}|^2 & a_{n1}b_{n1}^* \\
\overline{a_{n1}} & |b_{n1}|^2
\end{bmatrix} = \begin{bmatrix}
c_{11} & c_{12} \\
c_{21} & c_{22}
\end{bmatrix}
\]

Where:

- $|a_{n1}|^2$ and $|b_{n1}|^2$ are time-averaged noise power in 1 Hz bandwidth.
- $a_{n1}b_{n1}^*$ and $\overline{a_{n1}}a_{n1}$ are time-averaged cross correlation terms, correlation of $a_{n1}$ to $b_{n1}$.
- Overbars represent time-averaging
- Star superscripts represent complex conjugation

Noise Parameters

- **GammaOpt** (Optimum Complex Reflection Coefficient) - The optimal impedance for the noise figure measurement. Select the data format to display GammaOpt in terms of Log Mag, Lin Mag, Phase, Unwrapped Phase, Real, Imaginary, Polar, or on a Smith Chart.
- **NF_{min}** - The minimum noise figure that occurs at GammaOpt. NF_{min} is a scalar quantity that can be displayed as Log Mag, Lin Mag, or Real.
- **R_n** (Noise Resistance) - Specifies the rate of change of the level of noise when varying the source impedance. R_n is a scalar quantity in units of ohms that should be displayed in Lin Mag or Real format.
Note: Rn, as a measurement parameter, is not normalized. When the value of Rn is written to an S2P file, it is normalized (Rn / Zo). When an S2P file is recalled, the normalized Rn is multiplied by the system impedance to obtain Rn.

- **NCorr_11, NCorr_21, NCorr_12, NCorr_22** - The NCorr_11 and NCorr_22 terms are effective noise temperature, normalized to 290 K. Both terms are time-averaged, noise-wave powers referred to the input of the DUT, where NCorr_11 is the forward wave (noise going through the device towards the output), and NCorr_22 is the reverse noise wave (noise coming out of port 1 of the DUT, going back towards the source).

  To convert to available noise power, multiply the terms by 290*k*B where:

  - k = Boltzmanns constant
  - B = system bandwidth

---

**Standard Parameters that are offered** (Amplifiers-only)

- **S-parameters**: S11, S21, S22, S12
- **Unratioed parameters** using the following notation: (Receiver, source port). These parameters REPLACE the active measurement. To do this (from front-panel ONLY), press **Meas**, then **More**, then **Receivers**.

  - (R1,1), (R2,2), (A,1), (A,2), (B,1), (B,2)

---

**Save Noise Data**

To save noise data, click **File**, then **Save Data As**. Then select from the following **Save As Types**:

- (**.prn**), (**.cti**), (**.csv**), (**.mdf**) - Noise Figure data can be saved ONLY with these choices. PRN saves only the active trace. CITI formatted, CSV Formatted, and MDF can save all displayed traces. Learn more about these formats.

- (**.s2p**) - Saves S-parameter data only after performing a Noise calibration. This data is saved regardless of which noise measurement is active or displayed. Learn more about **.s2p** data.

**Trace and Noise parameter (**.s2p**)** - Saves S-parameter data, then the Noise Parameters. This data is saved regardless of which noise measurement is active or displayed. When the vector calibration is not enabled or if the noise parameters are not realizable, the noise parameters have no calculated value. In this instance, the following values are displayed instead:

  - **GammaOpt** = 0
  - **NFmin** = 50 ohm noise figure
  - **Rn** = Zo / 4 * (F - 1). This equation is how Rn is currently calculated for ill-conditioned data. F is the
noise factor where \( F \) is related to the noise correlation value \( c_{11} \) and the normalized noise temperature \( T_n \) by \( F = 1 + c_{11} = 1 + T_n \) so that \( R_n = \left( \frac{Z_0}{4} \right) \times c_{11} \)

- **NoiseCorr (*.nco)** - Saves Noise Correlation data regardless of which noise measurement is active or displayed. The *nco* file is a noise correlation matrix expressed in T-parameter form \( (C_{t11}, C_{t21}, C_{t12}, C_{t22}) \). These parameters are exactly the same as the Noise parameters \( NCorr_{11}, NCorr_{21}, NCorr_{12}, NCorr_{22} \) that can be displayed as traces.

- When the vector calibration is not enabled, this data is set to -200 dBm.

**How to start the Noise Figure Setup dialog**

**Using Hardkey/SoftTab/Softkey**

1. **Freq > Main > NF Setup....**

**Using a mouse**

1. Click **Stimulus**
2. Select **NF Setup...**

**Noise Figure Setup** dialog box help

**Note:** In this topic, the term **Jitter** is used to describe the trace-to-trace fluctuations in a measurement. In other topics, this is called 'trace noise'.

**Bandwidth/Average**

The following settings work together to achieve the optimum balance of measurement accuracy versus speed:

- **Noise Bandwidth**  Increase the bandwidth to reduce the amount of trace noise on the noise power or noise figure measurement (jitter). However, a wider setting reduces the frequency resolution of the measurement. The noise bandwidth setting should always be smaller than the bandwidth of the DUT. The noise bandwidth setting is used only while measuring noise powers, and is independent from the **IF bandwidth setting** used to measure S-parameters. Noise figure is
The calibration and measurement should be performed using the SAME noise bandwidth. When the noise bandwidth is changed after calibration, noise figure measurements can change by 0.5 dB or more, depending on the DUT frequency range, gain, and noise figure.

**Note:** The Noise Bandwidth may be adjusted automatically at low frequencies according to the following table. At each data point frequency, if the specified Noise BW is higher than that shown in the table, the Noise BW is set to the max value in the table.

<table>
<thead>

</tbody>
</table>

**Note:** Use Power Meter calibration method is NOT available when the Noise Bandwidth is 8 MHz or 24 MHz.

**Average Number** Increase the number of averages to reduce jitter. This also reduces measurement speed. For maximum accuracy, use the following recommendations for the noise calibration. When using the noise receivers, 10 noise averages is recommended. When using the standard receivers, at least 100 averages are recommended.

During a measurement, the gain of the DUT helps overcome the noise of the VNA receivers, so the number of noise averages can be reduced to improve measurement speed with minimal or no degradation to measurement accuracy.

**Use Narrowband Compensation**

The mathematics of noise figure assumes that the gain of the DUT is constant over the bandwidth of the noise receiver. The following image illustrates a case in which the gain (S21) of the DUT falls off sharply outside the passband region. When the VNA measures noise figure at the frequency indicated by the solid vertical line using a 4 MHz noise bandwidth, standard noise figure calculations assume the gain to equal its midpoint value (dashed horizontal line) over the
entire 4 MHz bandwidth. This assumption yields a composite gain-bandwidth value that is lower than the actual value, which in turn results in a noise figure value that is too high. This is the reason for the bump in the displayed NF value at this frequency and surrounding frequencies.

In the following image, Narrowband Compensation combines DUT measurements with characteristics of the noise receiver, which accommodates changes in DUT gain over the receiver bandwidth. The result is a better gain-bandwidth value of the system. Notice how the peaks and valleys of the NF measurement disappear when narrowband compensation is applied.

Notes on using Narrowband Compensation:
Can be used with either option 028 (Noise figure measurements using standard receivers) or 029 (Fully Corrected Noise Figure).

- With option 029 (NF receiver) Narrowband Compensation is available only for the 800 kHz, 2 MHz, and 4 MHz noise bandwidths.
- With option 028 (Standard VNA receivers) you **MUST** re-configure the front panel loops. Learn how.

Can be used with both Scalar and Vector NF calibrations, on either NF or NFX channels.

- The ON / Off state has no effect on calibration. In other words, it does not matter if Narrowband Compensation is On or Off while a noise calibration is being performed.
- Is applied only when corrected DUT measurements are made. If correction is turned off, it has no effect.
- Can be ON or Off while the NF channel is in Hold mode, and it will modify the NF trace appropriately. There is no need to re-sweep.

**Noise Receiver**

**NA (Network Analyzer) Receiver** (Opt 028) - Use a standard VNA receiver to measure noise figure.

- Connect the DUT to any VNA ports. For vector noise figure measurements, connect the noise tuner to the source port.
- The gain plus noise figure of the DUT minus cable loss must be at least 40 dB (**G+ NF - Loss > 40 dB**). This ensures that there is sufficient DUT noise power for the VNA to measure. Learn more.
- Additional filtering may be required. Learn more.

**Noise Receiver** (Opt 029) - Use internal low-noise receivers to measure noise figure.

- Opt 029 measures devices with noise figure values ranging from about 0 to 50 dB and devices with GAIN ranging from about -40 to +60 dB. Learn more.
- Amplifiers with higher gain can be measured by adding an attenuator to the output of DUT and using **fixture de-embedding** to remove the attenuator loss. An alternative for measuring high-gain devices is to use the standard receivers (Opt 028) as they have a higher compression level.

**Receiver Gain**

This setting is NOT available when Noise Receiver is set to **NA (Network Analyzer) Receiver** (Opt 028).

With knowledge of your DUT gain, set the appropriate amount of receiver gain in order to optimize
the power level at the noise receiver.

The following values reflect the SUM of the DUT gain (dB) **PLUS** NF (dB). For example: DUT gain = 20 dB; NF = 10 dB; SUM = 30 dB.

- Select **High** if the SUM is relatively low (<30 dB).
- Select **Medium** if the SUM is about average (20 dB to 45 dB).
- Select **Low** if the SUM is relatively high (>35 dB).

There is considerable overlap in these settings. Because all three gain settings are calibrated with each Noise Calibration, this setting can be changed after calibration to achieve the least amount of jitter without overpowering the noise receiver.

One of following messages appears when too much power is detected at the noise receiver:

- **Compression in noise receiver: excess signal** - The noise receiver is likely compressing. NF results are possibly not accurate. Select a lower gain setting.
- **Compression in noise receiver: gain has been limited** - The gain has been limited to avoid damage to the receiver. NF results are NOT accurate. Select a lower gain setting.
- **ADC over-range in noise receiver: excess signal** - Often caused by a CW signal, an oscillation, or LO feedthru during an NF measurement. Find and correct the cause, or try a lower gain setting.

Only ONE gain setting can be used for the entire frequency range of your noise measurement. Therefore, it may be necessary to use two noise channels with different frequency ranges and gain settings to achieve the very highest noise figure accuracy.

**Ambient Temperature**

**Note:** This setting is only used for calibrated noise figure measurements, but has no effect in an uncalibrated noise figure channel. The default value is used for uncalibrated measurements.

Enter the equivalent port 1 temperature at the time of the measurement, in Kelvin (K). One can use a thermometer to measure the temperature of the input cable.

In the case of full vector correction, it is the temperature of the Ecal Tuner (31 °C or 304.15K) minus the loss effect of the cable from the tuner to the DUT; both internal and external Ecals used as tuners have the same internal heater to heat to 31 °C.

For scalar it is the temperature of the internal load (such as the internal step attenuator) minus the loss of the cable, typically around 297K.
The cable loss compensation is computed from \(\text{Tambient} = T_{\text{pna\_source}} \cdot |S21|^2 + (1-|S21|^2) \cdot T_{\text{cable}}\) where \(S21\) is the loss of the port 1 cable, \(T_{\text{cable}}\) is the temperature of the cable, and \(T_{\text{pna\_source}}\) is the temperature of the either the Ecal used as a tuner, for full vector, or the temperature of the internal load for scalar calibration. \(T_{\text{ecal}}\) is typically 304.15K; the internal load is typically around 297K (if the attenuator internally is set to 10 dB or more) or 303K if the internal source attenuator is set to 0. The attenuator is physically located near the input of the air flow and so it is very close to the external ambient temperature, but with 0 dB setting, the temperature of the internal source becomes the effective input temperature and it is a little warmer at about 6 degrees rise above ambient.

This ambient temperature number has an inverse relationship to the noise figure. When using the effective noise temperature (\(Te\)) format, a 3 degree increase in the ambient temperature will make the calibration measurement result drop 3 degrees, which will then have an effect on subsequent noise figure measurements. One can directly measure the port 1 equivalent temperature by connecting port 1 to port 2 with a low loss through, and measuring the mean value directly. Because the noise value is quite low, averaging or using trace statistics should be used to find this value.

**Impedance States**

**Noise Tuner** Displays the ECal module to be used as a noise tuner. Select the Noise Tuner during calibration on the Select Cal Method dialog.

**Max Acquired Impedance States** Select the number of impedance states in which to make noise measurements. At least FOUR impedance states are required. Learn more.

**Power Tab - Noise Figure** dialog box help

![Power Tab - Noise Figure](image)

**Note:** S-parameter power settings are critical for accurate noise figure measurements. [See Noise Figure Measurement Tips.]

Configures RF power settings for the S-parameter measurements that occur before noise measurements. Input power to the DUT is turned OFF during noise measurements.

These settings can also be made from the normal **Power setting** locations.
**Power ON (All channels)**  Check to turn RF Power ON for all channels.

**DUT Input Port**

- Opt 028 - Select a VNA port to be connected to the DUT input.
- Opt 029 Scalar Noise Figure - Select a VNA port other than port 2.
- Opt 029 Vector Noise Figure - The DUT input CAN be connected to any VNA port other than port 2. However, without a noise tuner bypass switch, measurements on other channels that use the same source port will always go through the noise tuner. The noise tuner must be connected to the source loop of the selected port.

**Note:** Input power levels are critical for accurate noise figure measurements. [Learn more.](#)

**Power Level**  The input power to the DUT during S-parameter measurements.

**Source Attenuator Auto**  Check to automatically select the correct attenuation to achieve the specified input power. Clear, then select attenuator setting that is used achieve the specified Power Level. [Learn more about Source Attenuation.](#)

All VNA channels in continuous sweep must have the same attenuation value. [Learn more.](#)

**Receiver Attenuator**  Specifies the receiver attenuator setting for input port.

**Source Leveling**  Specifies the leveling mode. Choose Internal.  Open Loop should only be used when doing Wideband Pulse measurements (not available with Noise figure measurements).

**DUT Output Port**

- Opt 028 - Select a VNA port to be connected to the DUT output.
- Opt 029 - Connect the DUT output to VNA port 2.

**Output Power**  Sets power level in to the output port for reverse sweeps. Port power is automatically uncoupled. Reverse sweeps are always applied to the DUT when Full 2-port correction is applied. [Enhanced Response Cal](#) is NOT available for noise figure measurements.

**Source Attenuator**  Specifies the source attenuator setting for reverse power.

**Receiver Attenuator**  Specifies the receiver attenuator setting for the output port. [Learn more about Receiver Attenuation.](#)

**Source Leveling**  Specifies the leveling mode. Choose Internal.
26.5 GHz Models

The orange line between CPLR THRU and SRC OUT represents the Noise Tuner.

50 GHz Models (Opt. 029)

Port 1 Noise Tuner Switch (Opt 029)

26.5 GHz

The orange line between CPLR THRU and SRC OUT represents the Noise Tuner.
**External** selects the external Noise Tuner for making noise figure measurements.

**Internal** bypasses the external Noise Tuner.

See **Important Notes** about managing this switch.

### 50 GHz Models

- Tuner - Represents the built-in Noise tuner.
- Bypass - Bypasses the built-in tuner

**Port 2 Noise Receiver Switch (Opt 029 All models)** allows you to make Noise Receiver measurements.

To prevent premature wear on the above two Noise switches, the VNA does not allow these switches to be thrown when sweeping a Noise channel and non-Noise channel. To make noise figure measurements and non-noise figure measurements in different channels and continuously trigger both, set these switches to the same state as the Noise channel:

- With the **non-noise figure channel** active, go to Noise Path Configurator.

- Set Noise Tuner switch to **External**. This routes source power to the front-panel loops, and to the Noise Tuner when connected. Use **CONT:ECAL:MOD:PATH:STATE** to set the internal state of the Noise Tuner to THRU, which creates a small amount of additional loss in the source path.

- Set Noise Receiver Switch to **Noise Receiver**.

### Noise Figure Measurement Tips

**Note:** In this topic, the term **Jitter** is used to describe the trace-to-trace fluctuations in a measurement. In other topics, this is called 'trace noise'.

**Option 029**

See **Opt 028 (NF with Standard Receiver)**

- Measures devices with noise figure values ranging from about 0 to 50 dB and devices with GAIN ranging from about -40 to +60 dB.

- Highest noise figure accuracy is attained when the sum of device noise figure + GAIN is between 0 dB to +70 dB.

- For highest noise figure accuracy and stability, there should be the least amount of electrical loss possible.
between the DUT output and VNA Port 2.

**Power level at the DUT Output - Opt 029**

S-parameters are used to measure the gain of the DUT before each series of noise measurements. Jitter in the S-parameter measurements corresponds directly to jitter in the noise measurements.

For best noise figure accuracy, the power level out of the DUT should be between 15 dB and 20 dB below the compression point of the DUT during the S-parameter portion of the noise figure measurement.

To reduce jitter, the power level at the B receiver (port 2) should be above approximately -20 dBm. Much below this level, S-parameter measurements have more jitter. Power must be below +10 dBm as the B receiver starts to compress at this point, although there is no warning or annotation that shows this condition is occurring in S-parameter measurements.

The best way to monitor power at the B receiver is to display a B,1 measurement. With your DUT in place and powered ON, change the input power to the device and note the power at the B receiver.

- For low-gain DUTs, use 5 dB of source attenuation to improve the uncorrected match of port 1.
- For high-gain DUTs, source and receiver attenuation may be required. Use the lowest possible attenuation values.

Attaining the optimum power level during calibration can also be challenging since calibration is performed without the DUT in place. Because of this, it is often necessary to set source power higher during the calibration than during the measurement. This will cause the CΔ annotation on the status bar.

Measurement results are accurate as long as the step attenuators and other configuration switches are in the same position and all receivers remain in their linear range (below +10 dBm).

It is best to find the optimum power and attenuation settings for both the calibration and subsequent noise measurements before performing a calibration.

**IF Bandwidth**

Jitter is further reduced by narrowing the IF bandwidth. If the calibration needs to be performed at a low source power, or with receiver attenuation due to high DUT gain, the IF bandwidth should be reduced during the calibration to reduce jitter. The IF bandwidth can then be increased to improve measurement speed. The CΔ annotation can be ignored when changing IFBW after calibration.

**Noise Settings**

See Noise Figure dialog box help for a complete description of these important settings.

**Temperature**

6177
Noise Figure measurements are extremely sensitive to temperature. As such, there are two settings that require an accurate temperature measurement: At the DUT input, and at the Noise Source connector.

### Interference

When measuring the noise figure of an unshielded device, like an amplifier on a printed-circuit board, it is very common to pick up interference from external signals such as cellular phones, wireless LAN, or mobile radios. This interference shows up as non-repeatable spikes in the measurement, as shown below.

![Interference Graph]

Usually, the interference adversely affects the noise figure measurement only at the frequency where it occurs. However, if the interference is large enough and present all of the time, it can cause the noise receivers to compress, which results in inaccurate measurements at many frequencies. In this case, the noise figure measurements should be done in a shielded environment like a screen room.

### Option 028

**Noise Figure of VNA receiver** - Option 028 gives you the flexibility to measure noise figure using a standard VNA receiver. For best measurement accuracy, the DUT excess noise power, which is gain plus noise figure minus cable loss in dB (G + NF - Loss), should meet or exceed the noise figure of the receiver. This is generally not a problem with very high-gain devices such as converters with approximately 60 dB of gain.

If your DUT is NOT a very high-gain device, you can re-configure the VNA front panel loops to increase receiver sensitivity.

**Re-configuring the front panel loops** - This configuration reverses the main arm and coupled arm of the test-port coupler (see following images). This increases the signal to the receiver port by about 15 dB, while lowering the available port power by the same amount. This is a good tradeoff for noise figure measurements.
Configure the **receiver port** front-panel loops to a vertical orientation as shown here.

The following table shows the excess noise that is **required** at various frequencies. These values assume the front-panel loops have been re-configured as shown above:

<table>
<thead>
<tr>
<th>Frequency range</th>
<th>Required Excess Noise Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 20 GHz:</td>
<td>30 dB</td>
</tr>
<tr>
<td>Up to 50 GHz:</td>
<td>40 dB</td>
</tr>
<tr>
<td>Up to 67 GHz:</td>
<td>45 dB</td>
</tr>
</tbody>
</table>

For devices that do NOT meet this requirement, a low-noise amplifier (LNA) must be added to the receiver loop (see following image). This boosts the noise power at the receiver by the gain of the LNA. The disadvantage is the possibility of measurement drift and receiver compression. Any change in the gain of the LNA will have an impact on measurements that use the receiver with the LNA, so frequent calibration may be required. Care should also be taken when setting the channel power (used during the S-parameter portion of the calibration, and the gain portion of the DUT measurement) to ensure that the added gain of the LNA does not cause receiver damage or compression. A filter is also required on the output of the LNA. Learn more.
Filtering Requirement (Option 028)

Opt 029 includes noise receivers with filtering to keep mixing-product noise out of the low-noise receivers. These filters are not available when measuring noise with the standard VNA receiver. Therefore, for best measurement accuracy, a filter should be used at the output of the DUT (or LNA preamp if used).

- A bandpass filter at the frequencies of interest can always be used.
- A lowpass filter can be used when the VNA is doing fundamental mixing (up to 26.5 GHz). The lowpass filter must pass the fundamental frequency of the measurement but suppress the third harmonic. A measurement at 1 GHz would need a lowpass filter with a cutoff below 3 GHz, while a 5 GHz measurement would need a filter with a cutoff below 15 GHz.
- A single highpass filter can often be used when the VNA is doing 3rd-harmonic mixing (from 26.5 to 67 GHz). Use a highpass filter with cutoff about 18 GHz for frequencies up to 50 GHz. For operation to 67 GHz, the filter cutoff would need to be above 23 GHz.

Using Noise Figure Traces in Equation Editor

In a Noise Power trace, the underlying unit is noise temperature.

\[ 10 \log_{10} \left( \text{temperature} \times 1000 \text{mw/w} \times 1.38 \times 10^{-23} \right) \]

\((1.38 \times 10^{-23} \text{ is Boltzmann's constant})\)

Any time you use Equation Editor on a Noise Power trace, the LogMag formatting will apply the above equation. Therefore, first select REAL format and then generate the equation.
The following screen is an example showing three traces: DUTNPD (DUT Noise Power Density), NF (Noise Figure), and S11 with the equation set to "***=10". Note that formatting for noise figure measurements is different than noise power measurements or temperature measurements.

**Radio-Frequency Electromagnetic Field Immunity**

When a 3Vm-1 radio-frequency electromagnetic field is applied to an PNA with Opt 029 according to IEC 61000-4-3:1995, degradation of performance may be observed. When the frequency of the incident field matches the frequency of a measured noise figure or gain, the values displayed will deviate from those expected. This phenomenon will only affect that specific frequency, and the analyzer will continue to perform to the specification at all other frequency sample points.

The VNA with Opt 029 may be unable to calibrate a chosen frequency sample point if the frequency matches that of an incident electromagnetic field.
This topic discusses Noise Figure on Converters:

Requirements and Limitations

Noise Figure on Converters requires Noise Figure (Option 0pt 028 or 029 and S93029A/B).

Learn more about Noise Figure requirements.

Limitations

- Upconverters OR downconverters ONLY (not both).
- Image rejection is NOT provided in NFX.

The following VNA features are NOT available with NFX:

- Analog Sweep (Stepped sweep mode only)
- Independent IFBW, Power Levels, or Sweep Time in a segment table is NOT supported.
- Log frequency sweeps
- ECaL User Characterization
- Time Domain
- Balanced measurements
- Save Formatted Citifile data.
- Some Fixturing Features
- External Test Set Control (Option S93551A/B)
- External DC Devices
- Pulse measurements
- See Frequency Limitations

- Option 205 or Option 425

- Segmented sweeps (an alternative is to set up a separate channel for each frequency band)

Embedded LO measurements ARE supported in NFX. Learn more.
How to Configure your Hardware

The PNA-X is extremely versatile, and can be configured in many ways to make NFX measurements. While not all conceivable configurations are documented here, a few of the most common examples are provided to show the basic concepts.

DUT Configuration

Learn more about connecting the DUT input and output to the VNA.

The DUT LO can be connected to an external source OR VNA internal second source (if available).

Select an LO Source on the Mixer Setup tab.

Note: Noise that is present on the LO source will be directly transferred to the DUT output. This noise can NOT be calibrated out of the noise measurement. Therefore, choose a low-noise source for the LO, such as an Keysight ESG or PSG, which is better than the VNA internal source.

External LO Source though Port 3 or Port 4 (4-port PNA-X only)

- Connect the DUT LO to PNA-X Port 3 or Port 4.
- Connect external source to rear-panel J7 (Rear-panel load on below diagram) for Port 3; J3 for Port 4.
  - For Port 3, NO switching is required.
  - For Port 4, switch Port 4 Bypass Switch to Rear Panel.

PNA-X Internal LO Source

- SRC 2 Out 1 or Out 2 on front-panel or 2-port / 2-source PNA-X
- Port 3 or Port 4 on 4-port PNA-X
**VNA Source 2 for LO on 4-port models**

---

**Path Configurator - Default configuration on PNA-X option 423**

- By default, Internal source2 (Src2) is supplied at ports 3 and 4.
- Bypass switches must be in "Thru Path"

---

**Using the Noise Figure Application**

Use the following general procedure to make measurement with the Noise Figure App:

1. Connect Tuner and Noise Source.
2. Create a Noise Figure Measurement.
3. Make Noise Figure Settings.
4. For Opt 029 and H29, copy your Noise Source ENR file to the VNA C:\Program Files(x86)\Keysight\Network Analyzer\Noise folder.
5. Perform Calibration
6. Connect the DUT. Learn more.
7. Measure Noise Figure.
8. **Optional** Click File, then Save to save Noise Figure data in the following **formats**: (available ONLY when NF correction is ON.)

- *.CTI  Citifile
- *.PRN
- *.nco  Noise Correlation Matrix data in S2P format. See Noise Model.

See Also: Measurement Tips

---

**Connect Noise Tuner and Noise Source**

1. Connect the **noise source** to the 28V connector on the PNA-X rear panel. **NOT required for Opt 028.** The Noise Source is turned ON and OFF automatically as needed during a calibration. Connect the noise tuner to Port 2 reference place when prompted during calibration.

2. Connect the **noise tuner** (ECal module). **NOT required** for 50 GHz models and **Scalar Noise Figure measurements.**

   a. On the VNA front panel, remove the **Port 1** jumper cable SOURCE OUT / CPLR THRU. Opt 028 allows Noise Figure measurements using any two VNA ports. Connect the noise tuner to the front-panel jumpers for the source (DUT input) port.

   b. Connect M-F tuner (N4691B-M0F) using the supplied cable (N5242-20137) and adapter (85052-60013).

   c. When using F-F ECal module (N4691B-00F), order a 3.5 mm M-M adapter (85052-60014).

---

**Create a Noise Figure Measurement**

1. On the VNA front panel, press **Meas > S-Param > Meas Class....**

2. Select **Noise Figure Converters**, then either:
OK delete the existing measurement, or

New Channel to create the measurement in a new channel.

3. A Noise Figure measurement is displayed. Do the following to add or change parameters to display.

### NFX Parameters

#### How to ADD NFX Parameters

1. Create an NFX channel.
2. Then do the following:

<table>
<thead>
<tr>
<th>Using Hardkey/SoftTab/Softkey</th>
<th>Using a mouse</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Press <strong>Trace</strong> &gt; <strong>Trace N</strong> &gt; <strong>Trace N</strong>.</td>
<td>1. Click Instrument</td>
</tr>
<tr>
<td>2. Press <strong>Trace</strong> &gt; <strong>Trace Setup</strong> &gt; <strong>Measure...</strong>.</td>
<td>2. Select Trace</td>
</tr>
<tr>
<td>3. Select a trace by pressing <strong>Trace</strong> &gt; <strong>Trace N</strong> &gt; <strong>Trace N</strong>.</td>
<td>3. Select Add Trace</td>
</tr>
<tr>
<td>4. Press <strong>Trace</strong> &gt; <strong>Trace Setup</strong> &gt; <strong>Measure...</strong>.</td>
<td>4. Click Instrument</td>
</tr>
<tr>
<td>5. Select a parameter.</td>
<td>5. Select Trace</td>
</tr>
<tr>
<td>6. Select <strong>Measure...</strong>.</td>
<td>6. Select <strong>Measure...</strong></td>
</tr>
</tbody>
</table>

#### How to CHANGE NFX Parameters

1. Create an NFX channel.
2. Select the parameter to change.
3. Then do the following:

<table>
<thead>
<tr>
<th>Using Hardkey/SoftTab/Softkey</th>
<th>Using a mouse</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Select a trace by pressing <strong>Trace</strong> &gt; <strong>Trace N</strong> &gt; <strong>Trace N</strong>.</td>
<td>1. Right-click on a trace.</td>
</tr>
<tr>
<td>2. Press <strong>Trace</strong> &gt; <strong>Trace Setup</strong> &gt; <strong>Measure...</strong>.</td>
<td>2. Select a parameter</td>
</tr>
<tr>
<td>3. Select a parameter.</td>
<td></td>
</tr>
</tbody>
</table>

The same Noise parameters that are available in the Noise Figure application are also available in the NFX application. Learn more.
In addition, the following Mixer and Raw Receiver parameters are available in an NFx channel:

### Mixer Parameters

- **SC21** - Conversion Loss
- **SC12** - Reverse Conversion Loss
- **S11** - Input match
- **S22** - Output match
- **IPWR** - Input power to mixer/converter. Same as R1 (Source1)
- **OPWR** - Output power to mixer/converter. Same as B (Source1)
- **RevIPWR** - Power applied to mixer/converter Output. Same as R2 (Source2)
- **RevOPWR** - Power measured at mixer/converter Input. Same as A (Source2)

### Raw Receiver Parameters

Specify a receiver to measure at LO1 frequencies with the notation:

- `<Receiver>LO1`
- For example: **ALO1** or **R1LO1**

Specify a receiver to measure using a source port, with the notation:

- `<Receiver>_<source port>`
- For example: **A_3** or **R1_1**

### How to start the Noise Figure Setup dialog

**Using Hardkey/SoftTab/Softkey**

1. **Freq** > **Main** > **NFX Setup...**

**Using a mouse**

1. Click **Stimulus**
2. Select **NFX Setup...**

### Valid Mixer Configuration / Sweep Type Combinations
The following are the **Valid Mixer Configurations:**

<table>
<thead>
<tr>
<th>Sweep Type</th>
<th>Input</th>
<th>LO</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear</td>
<td>Swept</td>
<td>Swept</td>
<td>Fixed</td>
</tr>
<tr>
<td>Linear</td>
<td>Swept</td>
<td>Fixed</td>
<td>Swept</td>
</tr>
<tr>
<td>CW</td>
<td>Fixed</td>
<td>Fixed</td>
<td>Fixed</td>
</tr>
<tr>
<td>CW</td>
<td>Fixed</td>
<td>Swept</td>
<td>Swept</td>
</tr>
</tbody>
</table>

For determining a valid mixer configuration with 2 LOs, one Fixed LO and one Swept is equivalent to having a single-stage Swept LO.

If you create an invalid Sweep Type / Mixer Configuration, a red message appears like the following:

```
ERROR: Input range must be swept in Linear sweep mode.
```

If this occurs, change the **Sweep Type** on the **Frequency** tab.

See other rules for configuring a mixer.

The following tabs are available on the NFX Setup dialog:

- Frequency
- Power
- Noise Figure Setup
- Mixer Frequency (separate topic)
- Mixer Power (separate topic)
- Mixer Setup (separate topic)
## Frequency tab - NFX Setup dialog box help

<table>
<thead>
<tr>
<th>Sweep Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear - Use for Swept Input parameters</td>
</tr>
<tr>
<td>CW Frequency - Use for Fixed Input parameters</td>
</tr>
</tbody>
</table>

### X-Axis Display

Annotation: Select the frequency range to display on the X-axis.

### Sweep Settings

---

**Noise Path Configurator** dialog box help

Learn about this and the Path Configuration dialog for the 50 GHz models.
This dialog is identical to the Noise Figure Setup for amplifier EXCEPT for the following setting. Learn about the rest of this dialog.

**Enable Source Pulling for S-Parameters** (For mixers with low reverse isolation). When checked, during S22 (output match) measurements, the noise tuner is switched to present different impedance states to the DUT input. From these measurements, S22 is computed as though the input is seeing a 50 ohm match. This requires more sweeps. Check this box when the converter has low reverse isolation, as is the case when the NO output path is NOT padded with attenuation. Otherwise, clear this checkbox as S22 measurements will not be improved.

An accurate S22 measurement is essential when measuring S-parameters during an NFX calibration.

Calibration for Noise Figure on Amplifiers and Converters (NFX)

This topic discusses calibration for both Noise Figure on Amplifiers and Noise Figure on Converters (NFX).

- Overview
- How to Perform a Noise Figure Cal
  - Select Calibration Method
  - Configure Noise Source
  - Select DUT Connectors and Cal Kits
  - Measure Standards Steps
  - NFX Calibration
  - Validate Noise Source Cal

See Also

Noise Figure and TRL Cal

See Noise Figure and NFX Applications

Noise Figure Calibration Overview

**Note:** Noise Figure results are NOT at all accurate without a Noise Figure calibration.

NFX Calibration

Noise Figure calibration is very similar for both amplifiers and converters (NFX).

- NFX does NOT offer ‘S-params ONLY’ calibration.
- NFX includes an optional LO Power Cal.
- NFX Cal may generate a Cal Kit Frequency Error message. Learn more.
Calibrating the Noise Receivers

**Note:** The term 'noise receiver' is used here to refer to the receiver that is used to measure noise. It can be a standard VNA receiver or the dedicated noise receivers that are provided with Opt. 029.

The noise figure calibration process is different depending on if a Noise Source or a VNA source (calibrated with a power meter) is used to calibrate the noise receiver.

**Using a Power Meter**

When 'Use Power Meter' is selected on the 'Select Cal Method' dialog, a power meter is used in place of a noise source to characterize the noise receiver. **IMPORTANT: The power cal step must be completed first when acquiring the calibration.**

The process happens in three steps:

1. A Source Power Cal is performed at the port connected to the DUT's input, with a power level that is specified on the first measurement step of the calibration wizard.

2. A THRU connection is made from the calibrated source port to the specified noise receiver port. The gain of the noise receiver is then measured, as well as the receiver's noise floor.

3. With the THRU connection in place, the swept-frequency response of the noise bandwidth filter is measured. Since the noise receiver uses double-sideband homodyne mixing, the user sees a symmetrical response representing the low- and high-side responses, with a notch in the middle that nulls out the DC response. From the measured filter shape, the equivalent noise bandwidth is calculated. This information combined with the data from step 2 gives the gain-bandwidth product and noise figure of the noise receiver.

The following are variations to this process depending on the type of noise receiver selected.

**Using the low-noise (Opt 029) receiver:**

a. Step 3 (measure the frequency response of the noise bandwidth filter) is always performed, over the frequency range specified in the noise figure channel.

b. The gain-bandwidth information is contained within the noise figure calset.

c. **Note:** 'Use Power Meter' is NOT allowed when the Noise bandwidth is set to 8 MHz or 24 MHz.

d. Noise averaging is not automatically turned on.

**Using a standard receiver:**

a. Step 3 (measure the frequency response of the noise bandwidth filter) is performed one time for each noise bandwidth and each measurement receiver. When this step occurs, it happens over the full frequency range of the VNA. Therefore, a broadband connection must be ensured -- there should be
NO filtering in the thru path. For example, a wave-guide-to-coax adapter, which has a high-pass frequency response, should NOT be included.

b. After the initial cal, the noise bandwidth data is saved to an xml file and reused for subsequent noise calibrations. As new noise bandwidths and receivers are selected, new data is appended to the xml file. If you suspect that the xml file might contain bad values for the noise filter bandwidths, then delete:
   For XP: C:\Program Files\Keysight\Network Analyzer\Noise\noiseBW.xml
   For Win7: C:\programdata\Keysight\network analyzer\Noise\noiseBW.xml
This will cause the noise-filter shape for the selected receiver to be remeasured the next time a noise cal is performed using a standard receiver.

c. Noise averaging is automatically turned on, with a default value of 100 noise averages. This value can be modified as necessary. Learn more about Noise Averaging.

Using a Noise Source (See Noise Source requirements). NOT used when measuring noise figure with Standard VNA receivers.

A Noise Source is a device that generates two very consistent levels of noise over its operating frequency range:

- Hot (On) - the Noise Source is biased in order to provide a high level of noise.
- Cold (Off) - the Noise Source is unbiased to provide ambient temperature noise level.

These levels are measured by the Noise Source manufacturer and provided in table and electronic format with each Noise Source by serial number. The electronic file is known as the ENR (Excess Noise Ratio) file.

1. The Noise Source is connected to the noise receiver through test port 2.

   **Note:** For highest accuracy, the noise source should be connected as close as possible (the least amount of electrical loss) to the VNA port 2 connector. This causes the largest difference between the Noise Source HOT (on) and COLD (off) settings.

2. The Noise Source is measured by the noise receivers at each measurement frequency. The differences between the known ENR noise levels and the measured noise levels are the noise error terms. These values are removed from subsequent noise measurements.

3. During the Noise Source measurements, noise averaging and noise bandwidth is automatically turned ON to the values that you specify. Learn more about Noise Averaging.

**Following the Noise Receiver Cal**

- **A 2-port S-parameter calibration** is performed on the noise figure channel. This is because S-parameters
are measured at each frequency step before a noise measurement. Also during the S-parameter cal, at least FOUR different impedance states are presented at port 2 in order to later characterize the noise generated by the noise receiver. This cal can be either a SOLT or TRL cal. See Noise Figure and TRL Cal.

- After calibration, correction is automatically turned ON. The VNA status bar shows VNC_2P (for Vector) or SNC_2P (for Scalar).

**How to Perform a Noise Figure Calibration**

- Make the noise figure channel the active channel.
- Connect the noise figure Tuner to the VNA (for Vector noise figure cal).

**Using Hardkey/SoftTab/Softkey**

1. Press CAL > Main > Smart Cal....

**Using a mouse**

1. Click Response
2. Select Cal
3. Select Smart Cal...

The following Cal Wizard pages are unique to noise figure calibration. The remaining pages that are presented are the same as those in the standard Cal Wizard SmartCal.

**Select Calibration Method** dialog box help

- Vector Noise - Comprehensive noise figure calibration
- S-Parameter Only - Does NOT calibrate the noise receivers. NOT offered with NFX.
- Scalar Noise - Calibration for scalar noise figure measurements. Learn more.

**Enable LO Power Cal** - NFX ONLY. Check to cause the Cal Wizard to guide you through a
Power Calibration on the LO source.

**Note:** NO correction is provided for an adapter that may be used to connect the power sensor to the LO source.

### Noise Tuner

- Not available when Scalar Noise is selected.
- Select from the ECal modules that are connected to the USB.
- For 50 GHz Noise Receivers, select "Internal" to use the built-in Noise Tuner. Learn more.

### Orientation

**AutoOrient Tuner**  Check to allow the noise tuner orientation to be auto-detected. When cleared, use the following two fields to provide manual orientation of the noise tuner.

**Tuner In (SOURCE OUT) / Tuner Out (CPLRTHRU):** Specify the ECal module labels that are connected to the VNA front panel jumper connectors. Learn how to connect the noise tuner.

**Detect Tuners**  Click to re-detect the Noise Tuners (ECal modules) that are connected to the USB. If the ECal module is not detected, check the USB connection, then click this button. The label below the button indicates the total number of ECal modules that are connected to the USB.

### Receiver Characterization - Learn more about this process.

- **Use Noise Source** - A noise source is used to characterize the low-noise receivers.
- **Use Power Meter** - A Power Meter/Sensor is used to calibrate a VNA source, which then is used to characterize either the low-noise receivers or a VNA receiver. This selection is made for you and can NOT be changed when **NA Receiver** is selected on the Noise Figure Setup dialog.

**Note:** **Use Power Meter** is NOT available when the Noise Bandwidth is **8 MHz** or **24 MHz**. In the Noise Setup dialog, lower the Noise Bandwidth to allow this selection.
Configure Noise Source (Opt 029) dialog box help

**ENR File**  Select the Noise Source ENR file. If not already there, copy your Noise Source ENR file to the VNA C:\Program Files(x86)\Keysight\Network Analyzer\Noise folder. Then click **Browse** to find the ENR file.

**Clear ENR List**  Scroll to the bottom of the ENR list, then click to remove the selected ENR file. Then browse or select to find a new file.

**Edit ENR**  Click to launch the **ENR Editor** dialog box which is used to change or create ENR files. This is NOT usually necessary.

**Temperature**  Specify the current temperature at the Noise Source connector. The Noise source is kept ON during noise figure measurements. This results in the Noise Source being a few degrees warmer than Ambient temperature, and a more accurate calibration. See **Noise Figure tips** to learn more about the significance of temperature.

See **Noise Source requirements**.

Configure Noise Source dialog box help

**DC Bias Source using**  Select 28 V Rear Panel for PNA or External Source for PXI

**Use USB Noise Source**  Select the required noise source from selection.

**Temperature**  Specify the current temperature at the Noise Source connector. The Noise source is kept ON during noise figure measurements. This results in the Noise Source being a few degrees warmer than Ambient temperature, and a more accurate calibration. See **Noise Figure tips** to learn more about the significance of temperature.

See **Noise Source requirements**.
warmer than Ambient temperature, and a more accurate calibration. See Noise Figure tips to learn more about the significance of temperature.

**ENR File** Use USB Noise Source Internal File or select the Noise Source ENR file. If not already there, copy your Noise Source ENR file to the VNA C:/Program Files/Keysight/Network Analyzer/Noise folder. Then click **Browse** to find the ENR file.

**Clear ENR List** Scroll to the bottom of the ENR list, then click to remove the selected ENR file. Then browse or select to find a new file.

**Edit ENR** Click to launch the ENR Editor dialog box which is used to change or create ENR files. This is NOT usually necessary.

See Noise Source requirements.

Click either Create or Edit to launch the same dialog box, shown below.

- **Edit** populates all fields with existing data which can then be edited and stored.
- **Create** has empty fields except for frequencies.
**ENR Numeric Data**

Use **Previous** and **Next** buttons to scroll to **Entry #** to edit. Type **ENR** value in **dB**, then press **Enter**.

**Done**  Click when finished editing all values. Then click **Store ENR File** to save the file.

**Identifying Data**

**Model #** of the Noise Source. This can NOT be changed.

**Serial #** of the Noise Source.

**Temperature and Humidity** in which the Noise Source was calibrated. This is for information only. The ENR data is always normalized to 290 Kelvin.

**KeyBd**  launches a mouse-driven keyboard.

**Store ENR File**  Click to launch a dialog to save the new or edited ENR file.
Port 1 and Port 2

DUT (Device Under Test) Connectors Specify the connector and gender of the DUT.

Cal Kits Select the Cal Kit to be used to calibrate each test port. The list for each DUT Port displays kits having the same connector type as the DUT. Using incorrect calibration standards can significantly degrade measurement accuracy. Learn more.

Power Sensor Used to calibrate the source port. Specify the connector and gender of the Power Sensor.

Noise Src Used to calibrate the noise receivers (Opt 029). Specify the connector and gender of the Noise Source. The Keysight 346C has an "APC 3.5 male" connector.

Note: For highest accuracy, the noise source should be connected as close as possible to the VNA port 2 connector. This causes the largest difference between the Noise Source HOT (on) and COLD (off) settings.

For both Cal devices (power sensor and noise source, specify the connector type and gender. When the Cal device connector is NOT the same type and gender as the DUT Port connector, then for optimum accuracy, extra cal steps are used to measure and correct for the adapter that is used to connect the Cal device to the reference plane.

Select Ignored (at the bottom of the DUT Connectors list) to NOT compensate for the adapter.

Select the Cal Kit that will be used for that process.

De-embed power sensor adapter / noise source adapter / thru adapter The VNA uses the connector type and gender of the DUT along with the connector type and gender of the cal device to determine if an adapter removal operation is taking place AND whether or not that removal operation requires an additional cal step.

However, the use of the connector type can, in special cases, hide the need for the extra cal step. Check the "De-embed..." box in these cases to inform the VNA that the extra step is needed.

Such a case is illustrated below where the noise source is connected close to test port 2 for higher accuracy. If unchecked, the VNA would assume in this case that the Noise Source is connected to
the Thru standard at the port 1 (DUT input) reference plane.

**Source Cal Settings**  Click to launch the Source Power Cal (for apps) dialog. This dialog is used to set Power Meter / Sensor settings for both the Port 1 Power Cal, and the optional LO Power Cal.

**Modify Cal**  Check, then click Next, to Modify Cal (Standards AND Thru Method).

**Note:** Enhanced Response Calibration is NOT supported with noise figure.

---

**Measure Standards Steps** dialog box help

**Power Level** at which to perform the Power Cal.

It is usually best to set power level to 0 dBm at the power sensor because the power sensor is calibrated at that level. Lower power levels will yield a slower and noisier calibration.

However, with 20 dB of source attenuation (default NF setting), the VNA may not be capable of achieving this power level at higher frequencies. To check the max leveled power, view an R1 (port 1 reference receiver) trace over the frequency range of interest, then increase the power until roll-off appears. Power levels at the test port may be approximately 2 dB lower than at the R1 receiver.

If an external component is used between the VNA test port and the calibration reference plane,
then adjust the power level so that the power at the sensor is about 0 dBm if possible.

The current source attenuation value is shown on the dialog.

**LO Power Cal (Optional)** When enabled, perform a Source Power Cal at the DUT LO input. An LO must already be selected. Learn how. The power level of the LO source calibration is set on the NFX (LO) Power Tab.

**Connect Noise Source to the Port 2 measurement (reference) plane**

When the "De-embed Adapter.." boxes are checked, additional cal steps are required.

**Subsequent Steps**

- **Connect Port 1 to Port 2** - Connect port 1 reference plane to the port 2 reference plane using the required Thru standard or adapter.
- **Connect ECal to Ports 1 and 2** - Connect the ECal module between the port 1 reference plane and the port 2 reference plane.

**NFX Cal Kit Frequency Error**

When performing an NFX calibration with at least two ECal modules with different connector types, you may see the following error message.

This occurs because the VNA performs two full 2-port cals: one at the input frequencies with both connector types, and one at the output frequencies with both connector types. One of the ECal modules may not be defined over both frequency ranges.

To overcome this, you can perform a User-Characterization for the limited ECal module over the required frequency range. The VNA will present a warning, but it will be allowed. Learn how.

**Validate Noise Source Cal**

To validate a Noise Source calibration, connect the Noise Source to Port 2 and measure ENR.

Compare the measured values to the values in the ENR table.
How to manually turn the Noise Source ON | OFF

1. Press **Power > Main > Noise Source.**
When performing a TRL (or LRL, LRM) Cal as the 2-port S-parameter calibration of a Scalar or Vector Noise Figure measurement, you may see an error message that states that there are not enough standards for the cal.

This appears because, during the TRL calibration, at least **FIVE** impedance states must be presented to the Noise Receiver port. A typical TRL Cal Kit does not have 5 standards with the same connector type and gender as the DUT output port, and with different impedances.

To correct this situation, you must define additional standards for your TRL Cal Kit using the Edit Cal Kit dialog.

**Notes**

- Extra impedance standards are NOT required when you select and use an ECal module to perform the De-embed noise source adapter. In this case the ECal module is used to present five different impedance states to the Noise Receiver port.
- You can view the impedance match by measuring the standard over the frequency range of interest while viewing the Smith Chart format. Ideally, all five standards should have a response at different areas of the Smith Chart.

**To Modify the Cal Kit**

If the TRL Cal Kit is also defined as an SOLT kit, those **Selected Standards** will also be searched for an appropriate Reflect Standard.

1. Click **Edit** on the Error dialog, or **Cancel**.
2. Press **CAL > Cal Sets & Cal Kits > Cal Kit...**
3. Select the Cal Kit to be edited, then click **Edit...**
4. On the Edit Kit dialog, click the **TRL** tab.
5. For each of the following **Calibration Kit Classes**, note the **ID** number in the **Selected Standards** field:
For example, in the following image two shorts are defined as TRL REFLECT standards: ID numbers 7 and 14. Because they are already being used, you can NOT use these IDs for the additional standards required by the Noise Cal. You must select other standards available in the kit or you can define new standards.

6. Select the SOLT tab, then select any of the following Calibration Kit Class definitions:

   a. SA (Open)

   b. SB (Short)
7. In the **Available Standards** field, find a standard that is NOT one of the TRL IDs noted above. In this image, two opens are already assigned as SOLT standards, but because they are NOT assigned as TRL reflection standards, they are eligible to be additional standards.

8. If necessary, click >> to add it to the **Selected Standards**.

**Note:** Be sure to choose standards with the **same** connector gender as the DUT output port.

If no others exist, the following are good options:

- Offset Short
- Offset Open

**If your TRL Cal Kit does NOT have FIVE standards**

You can create a new device by reusing the LINE standard. However, instead of connecting both ends of the line, leave the line unterminated.

Although the following example creates an Open standard, during the calibration you will connect any line standard to the Noise Receiver port. The standard or definition is not important. It is simply another impedance state.

The following is an example of how to create this device.

1. On the Standards tab, click **Add**.
The following dialog appears:

Select **OPEN**, then click **OK**.

The following dialog appears:

3. Change the description to **Unterminated Line**. This will provide a prompt during the calibration.

4. Change **Connector** to match your physical line standard.

5. Note the new **Standard ID** number.

6. In the same manner as step 6 (above), on the **SOLT** tab, select **SA**.
7. Assign the new standard ID to the Selected Standards.

**Important:** Leave the new standard at the bottom of the Available standards list to which it was added. That way it will have no effect on the SOLT cals using that kit.
Narrowband Pulsed Application

Note: Beginning with the A.14.80.xx firmware release, the Narrowband Pulsed Application is no longer available. The Integrated Pulse App (Opt S93026A/B) replaces this application.

The Narrowband Pulsed Application is a Visual Basic program that provides a user interface for making pulsed measurements.

In this topic:

- Required Options
- Connecting External Pulse Generators
- Using the Narrowband Pulsed Application
- How to Configure Pulse Generators and Receivers
- Calibration in Pulse Mode
- Pulse Profiling
- Signal Reduction versus Gate Width
- Pulsed Frequency Converter Measurements
- Writing your own Narrowband Pulsed Application

- Enhanced Pulse Measurement Capabilities
- Support for Internal Pulse Generators / Modulators (PNA-X only)

See Also

- Learn about the Wideband Pulsed Application.
- For more conceptual information see our Pulsed Measurement App Notes.
- See PNA-X Block Diagram of IF Path / Pulse Generators / Source Modulation
- Programming commands

Other IF Access Topics
Required Options and Equipment

The VNA H08 option provides the Narrowband Pulsed Application. The following options are also required. If your VNA does not have the required options, a message is displayed on the screen. For more information, see Pulsed-RF Measurements Configuration Guide.

Models

- PNA-X Opt 224 (2-port Dual Source) select the 2-port Dual Source Configuration in the Path Configuration dialog to provide Pulse modulation on both port 1 and port 2.
- Use the Pulse I/O connector to access the internal pulse generators.
- See the PNA-X IF Path Configuration block diagram which includes the Pulse Modulators and Generators.

Other VNA Models

- PNA-L models: H08 NOT available.
- Keysight 81104A or 81110A Pulse Generator with ONLY the 81105A or 81111A output modules. The 81112A module does NOT have selectable 50 ohm/1K ohm output impedance/load compensation to drive the 1K ohm VNA IF gates. For more information, see the 81100 Family of Pulse Pattern Generators Technical Specifications at: http://literature.cdn.Keysight.com/litweb/pdf/5980-1215E.pdf

Connecting External Pulse Generators to the Z5623A H81

Each 81110A Pulse Generator has two output modules. Each output can drive a VNA IF Receiver or Source Modulation (Z5623A H81). Connect the Pulse Generators as follows:

81110A front panel connectors

- Connect GPIB cables to the 81110A and VNA.
- Connect the VNA 10 MHz Ref Out to the 81110A 10 MHz IN.
- If using two 81110As for a total of 4 outputs, then connect the TRIGGER OUT of one to the EXT INPUT of the other 81110A.
Connect the 81110A OUTPUTs to the VNA rear panel IF inputs to be gated. The outputs are mapped in the Pulsed Generator Configuration dialog box.

Connect the Z5623A H81Pulse Test Set (optional) to the VNA front-panel port 1 loops as follows:

<table>
<thead>
<tr>
<th>VNA</th>
<th>H81</th>
</tr>
</thead>
<tbody>
<tr>
<td>Src Out</td>
<td>Source IN</td>
</tr>
<tr>
<td>CPLR</td>
<td>CPLR</td>
</tr>
<tr>
<td>THRU</td>
<td>THRU</td>
</tr>
<tr>
<td>RCVR R1 IN</td>
<td>RCVR R1 Out</td>
</tr>
</tbody>
</table>

Using the Narrowband Pulsed Application

How to start the Narrowband Pulsed Application

Using **Hardkey/SoftTab/Softkey**

1. Press **Macro > Pulse**

Using a mouse

1. Click **Utility**
2. Select **Macro**
3. Select **Pulse**

See Also

- See programming commands to launch the Macro remotely.
- See how to write your own custom Narrowband Pulsed Application.

Keypad Data Entry

The VNA front-panel Numeric Entry and Navigation keys can be used for dialog box input. Also, a
keyboard can be used to enter values, including alpha characters for prefixes (for example, \texttt{u} for usec.) . After typing values, first press \texttt{Enter}, then press \texttt{Tab} to go to the next field.

The following is an image of the main dialog box:

![Agilent PNA Pulse Application dialog box help](image)

**Pulsed Application Main** dialog box help

\textbf{Note:} An error message may appear on the VNA stating that the response frequency has exceeded the maximum allowed frequency.

The Narrowband Pulsed Application may set the offset frequency (option S93080A) of the VNA to some value other than zero (the default value). If the stop frequency is set to the maximum of the VNA model, then the error message will appear.

To fix this, set the stop frequency to a value that is at least 2 kHz less than the maximum allowed. For example, if you have a 20 GHz VNA, and the stop frequency is set to 20 GHz, and the error message appears, then set the stop frequency to 19.999998 GHz.

See Block Diagram of IF Path / Pulse Generators / Source Modulation

**Configure**

You can configure more than one channel to make pulsed measurements, but the channels must use the same pulse generator settings.
Only the Keysight 81110A Pulse Generator is supported with the Narrowband Pulsed Application. Refer to the 81110A documentation for pulse repetition frequency and duty cycle capabilities.

**See Also**

- Configure Receivers
- Converter Measurements

**Edit / Undo**  Pulse Application settings revert to those when Apply was last pressed.

**Desired PRF and IFBW**  Enter the DESIRED values. When Calculate is pressed, one or both of these values may change.

- **Pulse Repetition Frequency (PRF)**: Frequency of the pulses from the Pulse Generator.
- **Pulse Repetition Interval**: $1/\text{PRF}$  Changes to either PRF or this setting changes both.
- **Receiver IF Bandwidth**: IF Bandwidth of the VNA. Choose a setting from 1 Hz to 10 KHz.
- **Fixed PRF**  When checked, (default setting) the Calculate algorithm will NOT adjust the PRF, but only change the IF Bandwidth. When cleared, both the PRF and IF Bandwidth values are adjusted as necessary.

**Note:** On VNA's with DSP version 4, the Calculate algorithm will NOT find nulling at several PRF frequencies. If this error is returned, add a small offset to the PRF (for example, 2.1 MHz instead of 2 MHz) or clear the Fixed PRF checkbox.

**Modulation/Gates**  The Source Modulation and four VNA receiver gates can each have their own, or share, Pulse Generator outputs. Shared outputs have identical Width and Delay values. To configure and enable outputs, click Configure, then Pulse Generators to launch the Pulsed Generator Configuration dialog box.

**Note:** Option 036 and 037 limits the Source Modulation width to 117 ns.

- **Width**  Pulse Width.
- **Delay**  The delay that occurs before the pulse.
**Duty Cycle** Calculated Duty Cycle of the source and each of the selected receivers. Updated when Calculate is pressed.

**Pulse Mode On** When this box is checked, the VNA is enabled for Pulsed measurements. The VNA Status Bar annotation indicates the following:

- **G** Internal IF gates enabled.
- **F** Filtering for Pulsed Measurements enabled.

**Apply** All selections are sent to the pulse generator and the active channel of the VNA.

**Calculate** All selections are calculated and valid PRF and IFBW values are entered in their fields. If these settings are not acceptable, try changing the values you previously entered and click Calculate again. When acceptable values are attained, click Apply to send these values to the pulse generator and VNA.

**Pulse Profile** Launches the Pulse Profile dialog box. Same as clicking View / Pulse Profile. If not available, check Pulse Mode ON, click Calculate, then Apply.

**Minimize** Click to minimize the dialog box to make changes in the VNA application. To see the dialog again, select Macro, Pulse, or turn the Status Bar ON.

**Save** All settings from the Narrowband Pulsed Application are saved in a *.ppf file. These settings are NOT saved with VNA instrument state.

**Recall** Restore settings from the specified *.ppf file that were previously saved.

**Close** Closes the dialog box without saving changes.
How to configure Pulse Generators / Modulators and Receivers

From the Pulse App main dialog box

Learn about...

- Configure Receiver Gain
- Converter Measurements
- **No Pulse Generators** When checked, the Narrowband Pulsed Application does NOT attempt to communicate with internal or external pulse generators. This setting is used for troubleshooting purposes.
- **No SW Gating** When checked, the improved SW gating sensitivity is turned OFF. This setting is used for troubleshooting purposes.

Pulsed Generator Configuration dialog box help

Notes:

- See Block Diagram of PNA-X IF Path / Pulse Generators / Source Modulation
- For PNA-X Opt 224 (2-port Dual Source) select the 2-port Dual Source Configuration in the Path
Configuration dialog to provide Pulse Modulation on both port 1 and port 2.

- This dialog may look different depending on the VNA model and number of receivers available.

Configures either the internal pulse generators (PNA-X models with relevant options), or Keysight 81110A Pulse Generator outputs. You can configure each 81110A Pulse Generator with either one or two 81111A output modules.

The Source Mod and four VNA receiver gates can each have their own, or shared, pulsed generators allowing identical Width and Delay values which are selected on the Main dialog.

To share an external generator output between one or more VNA inputs, use the same GPIB address and output module for each VNA input.

**Internal Pulse Gen Output** (available ONLY on the PNA-X opt S93025A/B)

Specify the Pulse Gen (1 through 4) to use to modulate each of the VNA receiver IF gates or Sources.

**External Pulse Generator settings**

- **GPIB Addr:** The GPIB address of the 81110A.
- **Output:** The output module of the 81110A.
- **Primary:** The 81110A that uses the 10 MHz reference signal from the VNA.
- **Enabled:** Turns the pulse output ON.

**External Gate/Modulator settings**

- **High:** Specify a 'TTL-High' voltage level
- **Low:** Specify a 'TTL-Low' voltage level
- **Ext Impedance:** Impedance of the modulator used to create the pulse.
- **Complement:** When this box is cleared, TTL HIGH is the pulse. When checked, TTL LOW is the pulse.

**Using Internal Modulators** When this box is checked, the voltage, impedance, and complement values are forced to settings that prevent damage to the internal modulator.

**Using Internal Pulse Generators** Makes the appropriate settings on this dialog available.

**Using Internal VNA gates** When this box is checked, the voltage, impedance, and complement values are forced to settings that prevent damage to the internal gates.
Receiver Gain Configuration dialog box help

See Block Diagram of PNA-X IF Path / Pulse Generators / Source Modulation

This dialog may look different depending on the VNA model and number of receivers available.

Sets the gain of each VNA receiver manually or automatically.

**Auto** - The VNA selects the best gain level to make pulsed measurements.

Use the following to manually set the gain for each receiver.

**Low** - about 0 dB of gain

**Medium** - about 17 dB of gain

**High** - about 24 dB of gain

The PNA-X has the following attenuation settings:

**Low** - 30 dB of attenuation

**Medium** - 15 dB of attenuation

**Hi** - 0 dB of attenuation

Calibration in Pulse Mode

To perform a calibration in pulse mode (option H08), first configure and apply the pulse parameters (PRF, Pulse Width, Delays, IF gating, and so forth) **before** calibrating the system. This will ensure the VNA is configured properly during the calibration and measurement.

When performing **Unknown Thru** or **TRL calibrations**, ALL receivers must be gated. Otherwise, the error
terms will not be correct after the calibration has completed. This can be accomplished by either having a separate pulse generator output for each of the IF gates, or by connecting pairs of the IF gates together with BNC-T's. For example, if the pulse generator does not have enough outputs, then connect the R1 and R2 IF gates to the same pulse generator output. Also, connect the A and B IF gates to either separate outputs (recommended) or one output (reduces flexibility). The error terms will then be valid after the calibration is complete.

**Pulse Profiling**

Pulse profiling provides a time domain view of the pulse envelope. Profiling is performed using a measurement technique that "walks" a narrow receiver "snapshot" across the width of the pulse. This is analogous to using a camera to take many small snapshots of a wide image, then piecing them together to form a single, panoramic view.

- Pulse Profiling can be performed using ratioed or unratioed measurements.
- Pulse Profiling is performed at a single CW frequency.

**How to perform Pulse Profiling**

From the Pulse App main dialog box,

Click the **Pulse Profile** button. or:

![Configure View Help Desired Pulse Profile](image)

If this setting is unavailable, check **Pulse Mode ON**, click **Calculate**, then **Apply**.
Learn about Pulse Profiling (scroll up)

See Block Diagram of PNA-X IF Path / Pulse Generators / Source Modulation

**Modulation / Gates**

These setting duplicate those found on the main Pulse App dialog box.

In Pulse Profile, the Gate Delay settings (highlighted in yellow) are significant only with certain Measurement Parameter and Couple Gates settings.

**Time Parameters**

**Start, Stop** These two combine to make the window of the assembled pulse profile. To view the entire pulse, the start and stop values must be at least as wide as the Source Modulation Width plus Delay value.

**Step** Each consecutive snapshot is incremented by this value until the stop value is reached. Therefore, the number of points for the pulse profile measurement can be calculated as: (Stop - Start) / Step. The higher the number of points, the longer it takes to make the measurement.

**Measurement Parameter**

**CW Freq.** Frequency of the VNA source.

**Source Port** The VNA port supplying the source power. Only required for single receiver (unratioed) measurements.
**Param(eter)** Only those receiver gates (and relevant measurements) that are configured in Pulsed Generator Configuration are available.

**Note:** When a single receiver (unratioed) is selected, **Gate Delay** Settings (highlighted in yellow on above dialog image) are ignored.

If the reference receiver gate is NOT configured, the average of the Source Modulation pulse is used as the reference. **For example:** With S21 Selected, but ONLY B receiver gate is configured, then...

- **B Gate is walked across the Source Modulation pulse.**
- **Source Modulation pulse average is used as reference (not gated).**

**Coupled Gates** Used when the appropriate receiver gates are configured for your **S-parameter** measurement ONLY. This setting is ignored when a single receiver (**Param**) is selected.

- **Uncoupled** (box cleared) The reference gate is FIXED at the delay setting as the test gate is walked across the Source Modulation pulse as dictated by the **Time Parameter** settings.

  **For example:**
  - **S21 Selected, B and R1 receiver gates configured, Gates Uncoupled**
    - **B Gate is walked across the Source Modulation pulse.**
    - **R1 gate is fixed at pulse width and delay setting.**

- **Coupled** (box checked) The reference gate is walked synchronously with the test gate as dictated by the **Time Parameter** settings. Only the **difference** between the test and reference gate delay values is significant; NOT the absolute values.
For example:
S21 Selected, B and R1 receiver gates configured, Gates Coupled

B gate delay = 3 microseconds,

R1 gate delay = 2 microseconds

Difference = 1 microsecond

B Gate is walked across the Source Modulation pulse.

R1 gate is fixed at pulse width and delay setting.

B gate leads R1 gate by 1 microsecond.

Data Format Log Magnitude, Linear Magnitude, or Phase (only available if S-parameter selected).

Buttons

Show Gates Allows you do change the receiver gating width and delay while looking at the results.

Apply Gate Settings Click after making changes to gate settings.

Continuous Sweep Check, then click Measure, to continuously measure pulse profiling.

Measure Click to start the pulse profile measurement. Becomes Stop when continuously sweeping.

Marker to Delay After making a measurement, you can drag the display maker to any point along the trace. Click this button and the marker time is entered into the Receiver Delay field on the main dialog box.

Save Data Saves time domain data to the VNA hard drive in any of the following formats:

- Touchstone (*.s1p)
- Comma delimited (*.prn)
- Citifile (*.cti)

Learn more about these data formats

Signal Reduction versus Gate Width
The following two figures show the performance of the internal IF gates as the width is narrowed.

The following is a zoomed image of the shaded area (above).

- The straight line shows the theoretical loss in dynamic range due to duty cycle effects when using narrowband detection.
The curved (red) line shows the actual measured performance of the gates.

The minimum gate width for <1dB deviation from theoretical is approximately 20ns.

See the specifications for the option H11 and option H08.

Pulsed Frequency Converter Measurements

The Narrowband Pulsed Application works with both FCA (option S93083A/B) and standard Frequency Offset (opt S93080A) measurements. On the Configure menu, check Converter Measurements. When checked, this setting prevents the Narrowband Pulsed Application from overwriting frequency offset values. This may limit the number of PRF and IFBW solutions that are returned when Calculate is pressed on the main Pulsed Application dialog box.

Note: Pulse Profiling can NOT be performed with frequency converter measurements.

Writing your own Narrowband Pulsed Application

You can use the Narrowband Pulsed Application or use an example program as a template for making your own Narrowband Pulsed Application.

The Narrowband Pulsed Application uses a custom .dll to perform the calculations that are necessary to make pulsed measurements. Use the COM Method below to send and return values to agilentPNApulsed.dll. Then use SCPI or COM commands to control the VNA.

<table>
<thead>
<tr>
<th>COM Example Program</th>
<th>PNA-X Create</th>

</tr>
</tbody>
</table>

6225
To create your own Narrowband Pulsed Application, or run the Narrowband Pulsed Application from a remote PC, you must do the following:

1. Copy the following files from the VNA C:\program files(x86)\Keysight\network analyzer\ to a directory on your PC.
   - agilentpnapulsed.dll
   - OffsetList.txt
   - prfbw.txt
   - prfbwmixer.txt

2. To register the ActiveX DLL in Microsoft Windows Operating System:
   - From a command prompt on your PC, navigate to the directory where you copied the DLL.
   - Type: `regsvr32 agilentpnapulsed.dll` and press Enter

For Operating Systems other than Windows, see their associated help files to learn how to register DLL files.
Wideband Pulsed Application

Note: The PNA-X with Opt S93025A/B and Opt S93026A/B has an integrated Pulse Measurement Setup that makes this application no longer necessary on the PNA-X.

The Wideband Pulsed Application configures the PNA-X internal pulse generators and modulators for measuring pulsed S-parameters using the wideband mode detection technique.

The Wideband Pulse Application is designed to be used with the PNA-X with Opt 021, 022, and S93025A/B.

Note: Wideband Pulse application is NOT supported on the E836x and PNA-L models.

See Also

- To learn more about wideband detection, see Application Note 1408-12.
- See a Visual Basic example: Create a Wideband Pulsed Measurement using the PNA-X
- Learn about the Narrowband Pulsed Application.

Download and Install the Wideband Pulsed Application

This application is installed and run as a macro on the PNA-X. Learn more about macros.

2. Click the download link.
3. Save the downloaded file to the VNA hard drive.
4. Double-click the downloaded file to install the Wideband Pulsed Application on the VNA.
5. The application is saved on the VNA at C:\Program Files(x86)\Keysight\Network Analyzer\Applications\WB Pulse\Wideband_pulse.exe.
6. Configure the macro. Learn how.

To learn more about Wideband pulsed application, click Help in the application.
Overview

**Note:** The Phase Noise Application applies ONLY to PNA/PNA-X instruments with serial prefix 6021 and above.

The Option S93031xB Phase Noise application measures the phase noise of a DUT's output signal within a specified offset frequency range.

In this topic:

Features and Requirements

Features

- Absolute Phase Noise measurements
- AM noise measurement
- Spur identification and removal
- Automatic carrier search
- Extensible to mm-Wave

Requirements

- Phase Noise Option S93031xB
- 2-Port or 4-Port PNA/PNA-X instruments with serial prefix 6201 and above (new Direct Digital Synthesizers)
- Windows 10 operating system

Phase Noise Floor versus Frequency Plot

The noise floor for 2.4 GHz, 4.8 GHz, 9.6 GHz, and 19.2 GHz frequencies rises at an offset frequency of 300 kHz as shown in the following plot:
The following are typical hardware setups for measuring the phase noise of a device. The Option S93031xB Phase Noise application is installed on the PNA/PNA-X.
Phase Noise Display

The Phase Noise application measures the power density of the noise sideband relative to the power of
the carrier over a start/stop offset frequency. The offset frequency corresponds to the distance from the carrier frequency. The log-transformed phase noise is displayed in dBC/Hz.

The bottom of the display area shows the carrier frequency, carrier power, and the Phase Noise start and stop offset frequencies. The x-axis is the offset frequency range displayed on a logarithmic scale to allow viewing the full offset range. Also displayed is the delta frequency indicator next to the Carrier Frequency. The delta frequency displays the frequency from the nominal carrier frequency. The actual carrier is not tuned exactly to the nominal carrier frequency. The delta indicator displays this frequency difference.

If the sweep time is greater than 2 seconds, a sweep indicator is displayed at the bottom of the display area to provide sweep time percentage complete:

Noise tables showing Spurious, Integrated Noise, and Spot Noise data can be displayed below the trace area.

**Spurious Measurement**

Spurs can be analyzed using Spurious Sensibility or by defining Threshold levels.
Spurious Sensibility

Spurious Sensibility = Sensibility Value x Standard Deviation (or sigma).
The Spurious Table can be displayed below the trace area of the display showing Trace and Spur number, Offset frequency, Power level, and Jitter.

<table>
<thead>
<tr>
<th>Trace</th>
<th>Spur</th>
<th>Offset</th>
<th>Power</th>
<th>Jitter</th>

</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>59.905 Hz</td>
<td>-81.31 dBc</td>
<td>19.35 fs</td>
</tr>
</tbody>
</table>

**Integrated Noise Measurement**

Integrated noise is the single sideband noise integrated over a measurement bandwidth from a start/stop offset frequency. Up to four offset frequency ranges can be defined.

A weighting filter can be defined and saved to a file for later use. The weighting filters compensate external effects that affect the phase noise in the specified frequency ranges. When the weighting filters are applied, the trace data are corrected by the filter characteristics before the calculation of integrated noise.
Integrated Noise Table

The Integrated Noise Table can be displayed below the trace area of the display showing trace number, start/stop offset, weighting filename (if used) integrated noise, phase modulation measured in degrees and radians, residual FM (Hz) or residual AM (%), and jitter.

<table>
<thead>
<tr>

<td>10 MHz</td>
<td></td>
<td>-56.182 dBC</td>
<td>11.273 kHz</td>
<td>349.32 fs</td>
<td></td>
</tr>
</tbody>
</table>

Spot Noise Measurement

Spot Noise measurement are measurements made at specific frequencies. The measurements can be made at each decade, determined by the start/stop offset frequencies, up to six defined frequencies, or a combination of both decade and defined frequencies.
Spot Noise Table

The Spot Noise Table can be displayed below the trace area of the display showing the specific measurement frequencies and the phase noise in dBc/Hz.

<table>
<thead>

Phase Noise Graphical User Interface

The GUI consists of setup dialogs accessed by clicking on their corresponding tabs. In this way, configurations can be set up quickly. See Configuring Phase Noise for information about these dialogs.
Starting and Exiting Phase Noise

In this topic:

- Starting Phase Noise Application
- Exiting Phase Noise Application

Starting Phase Noise Application

How to start Phase Noise

Using Hardkey/SoftTab/Softkey

1. On the VNA, press **Meas > S-Param > Meas Class**....
2. Select **Phase Noise**, then click **OK**.
3. In the **Confirm Measurement Class Change** dialog, click **OK** to proceed or **Cancel** to exit.
4. The **Phase Noise** application is displayed (shown below).

Using a mouse

1. Click **Instrument**.
2. Select **Meas Class**....
3. Select **Phase Noise**, then click **OK**.
4. In the **Confirm Measurement Class Change** dialog, click **OK** to proceed or **Cancel** to exit.
5. The **Phase Noise** application is displayed (shown below).
Exiting Phase Noise Application

1. Select a different Measurement Class for the currently active channel.
Configuring Phase Noise

The Phase Noise dialog settings are contained within five tabs: **Sweep**, **RF Path**, **Spurious**, **Integrated Noise**, and **Spot Noise**.

In this topic:

- Create a Phase Noise Channel
- Opening the Phase Noise Dialog
- Sweep Tab in Dialog
- RF Path Tab in Dialog
- Source Tab in Dialog
- Spurious Tab in Dialog
- Integrated Noise Tab in Dialog
- Spot Noise Tab in Dialog

See Also

- Displaying Phase Noise Parameters
- Spectrum Analyzer Settings
- Phase Noise Marker Search Functions
- Phase Noise Measurement Examples
  - Setting Up a Phase Noise Measurement
  - Spurious Measurement
  - Integrated Noise Measurement
  - Spot Noise Measurement
  - AM Noise Measurement
- Phase Noise SCPI Programming Examples
  - Setting Up a Phase Noise Measurement
  - Setting Up a Source
  - Spurious Measurement
  - Integrated Noise Measurement
  - Spot Noise Measurement

Create a Phase Noise Channel
1. On the VNA front panel, press **Meas > S-Param > Meas Class...**.

2. Select **Phase Noise**, then either:
   - **OK** to delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

3. In the **Confirm Measurement Class Change** dialog, click **OK** to proceed or **Cancel** to exit.

4. The **Phase Noise** dialog is displayed.

**Opening the Phase Noise Dialog**

**Accessing Phase Noise Settings**

- **Using Hardkey / SoftTab / Softkey**
  1. Press **Setup > Main > Phase Noise Setup...**.

- **Using a mouse**
  1. Click **Stimulus**.
  2. Select **Phase Noise Setup...**.

**Sweep Tab in dialog help**

**Noise Type** - Selects between standard phase noise measurements and residual noise.
measurements.

**Phase Noise** - (Default) - Measures phase noise of a DUT. Select for single channel residual noise measurement when the input and output frequencies of the DUT are not the same. For example, frequency converters.

**Residual Noise** - Measures the additive phase noise of a DUT. This measurement is set up in the RF Path tab using DUT Input and DUT Output. Select for 2-channel residual noise measurement when the input and output frequencies of the DUT are the same. For example, amplifiers.

**Carrier Frequency** - Sets the carrier frequency. The range of the phase noise measurement is determined by the start/stop offset frequency which is relative to the carrier frequency.

**Carrier Threshold** - Sets the threshold to use during a carrier search.

**Start Offset** - Sets the start frequency of the phase measurement. This is an offset relative to the carrier frequency to position the measurement about the noise sideband to measure power density in dBc/Hz. For example, if the Start Offset is set to 1 MHz with a carrier frequency of 1 GHz, then the dBc/Hz phase noise measurement starts at 1.001 GHz. The minimum frequency is 0.1 Hz.

**Stop Offset** - Sets the stop frequency of the phase measurement. This is an offset relative to the carrier frequency to position the measurement about the noise sideband to measure power density in dBc/Hz. For example, if the Stop Offset is set to 10 MHz with a carrier frequency of 1 GHz, then the dBc/Hz phase noise measurement stops at 1.010 GHz. The maximum frequency is 10 MHz.

**RBW Ratio** - Sets the resolution bandwidth ratio, which is the specified resolution bandwidth percentage of every half decade offset frequency.

Example:

Start Offset = 1 kHz
Stop Offset = 100 kHz
RBW Ratio = 10%

1 kHz - 3 kHz: RBW = 100 Hz (10% of 1 kHz)
3 kHz - 10 kHz: RBW = 300 Hz (10% of 3 kHz)
10 kHz - 30 kHz: RBW = 1 kHz (10% of 10 kHz)
30 kHz - 100 kHz: RBW = 3 kHz (10% of 30 kHz)
**FFT Avg Factor** - Sets the FFT average factor number. The average factor is multiplied by the default average count, which changes for each frequency range. The default average count of the lower frequency range is 1 and at the higher offset frequency range is a larger average count.

**Note:** The minimum **RBW Ratio** setting relative to the maximum **FFT Avg Factor** setting are limited based on the frequency offset. The firmware restricts these settings if they exceed the limits.

**Noise Mode** - Sets the measurement speed and noise floor.

- **Fast** - Fastest measurement speed with highest noise floor.
- **Normal** - Between fastest and slowest measurement speed and noise floor.
- **Best** - Slowest measurement speed with lowest noise floor.

The zone boundaries and decimation factors change with noise mode as shown in the following example:

![Graph showing different modes of measurement](image)

**Defaults** button - Restores default phase noise settings.

**Apply** button - Applies setting changes and leaves the dialog box open to make more setting changes.
Measurement Type: Residual Noise

**VNA Input** - Sets the receiver input to use for the phase noise measurement.

**DUT Input/DUT Output** - Displayed when **Noise Type** in the **Sweep** tab is set to **Residual Noise**. Sets up ratios for residual phase noise measurements. For example, with DUT Input set to a1 and DUT Output set to b2, the additive phase noise at b2 relative to a1 is measured.
**Rcvr Atten** - Sets the attenuator on the test receiver.

**R F Path Configuration**... - Learn more

**Defaults** button - Restores default phase noise settings.

**Apply** button - Applies setting changes and leaves the dialog box open to make more setting changes.

---

### Source Tab in dialog help

![Source Tab in dialog help](image)

**Power On (All Channels)** Check to enable source power for all channels. Only turns power ON if the port State setting is ON.

**Port Powers Coupled**

- **Coupled** (checked) The power levels are the same at each test port. Set power at any test port and all test ports change to the same power level.
- **Uncoupled** (cleared) The power levels are set independently for each test port. Uncouple power, for example, if you want to measure the gain and reverse-isolation of a high-gain
amplifier. The power required for the input port of the amplifier is much lower than the power required for the output port. A power sweep can also be performed with uncoupled power. Learn more about Setting Independent Port Power.

Source Cells

Name - Lists the test ports through which an internal source is available. If an external source has been configured, it will appear at the bottom of the list.

State

- **ON** Source power is ALWAYS ON. Turning ON port 1 will also turn ON port 2 and vice versa. The same is true for port 3 and port 4. Learn about internal second source restrictions.

- **OFF** Source power is never ON, regardless of the measurement requirements. Use this setting to prevent damage to a sensitive DUT test port.

Frequency - Click in the cell, then click **Edit**, to start the **Frequency Settings** dialog (below).

![Frequency Settings Dialog](image)

Power - Sets the power level at the output of the source. Click in the cell, then click **Edit**, to start the **Power Settings** dialog (below).
Pulse - Enable/disable pulse measurements. Learn more.

Power and Attenuator... - Learn more

External Devices... - Learn more

Defaults button - Restores default phase noise settings.

Apply button - Applies setting changes and leaves the dialog box open to make more setting changes.
**Show Spurious Table** - Enable or disable displaying the spurious table below the trace display.

<table>
<thead>
<tr>
<th>Trace</th>
<th>Spur</th>
<th>Offset</th>
<th>Power</th>
<th>Jitter</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>59.905 Hz</td>
<td>-81.31 dBc</td>
<td>19.35 fs</td>
</tr>
</tbody>
</table>

**Trace** - Displays trace number(s).

**Spur** - Displays the spur number(s) per trace.

**Offset** - Offset frequency.

**Power** - Power level of the spur.

**Jitter** - The phase deviation in the time domain.

**Table Sort Order** - Sets the spurious table sorting by power or by offset.

**Select** -

**Enable Spur Analysis** - Enables and disables spurious analysis search markers. See Spurious Search.

**Spur Sensibility** - Sets the spurious sensibility value. The default is 3 (3 x standard deviation (sigma)).

**Example of Spurious Judgement Using Spurious Sensibility**
**Min. Spur Level** - Spurious data larger than this minimum spurious level will be omitted from the spurious data.

**Omit Displayed Spur** - Omits all displayed spurs.
**Defaults** button - Restores default phase noise settings.

**Apply** button - Applies setting changes and leaves the dialog box open to make more setting changes.

---

**Integrated Noise Tab in dialog help**

Show Integrated Noise Table - Enable or disable displaying the integrated noise table below the trace display. Integrated noise is the single sideband noise integrated over a measurement bandwidth from a start/stop frequency.

</table>

**Trace** - Displays trace number(s).

**Start Offset** - This is the same as the **Start Offset** defined in the **Sweep** tab.

**Stop Offset** - This is the same as the **Stop Offset** defined in the **Sweep** tab.

**Weighting Filter** - Displays the weighting filename or None for no weighting.

**Integ Noise** - Noise over a measurement bandwidth from the defined start/stop frequency.
**PM** - Phase Modulation measured in degrees and radians.

**FM/AM** - The FM/AM column displays a value depending on the measurement parameter. When the measurement parameter is Phase Noise (for example, PN_b2), the residual FM (Hz) is shown in the FM/AM column. When the measurement parameter is AM Noise (for example, AM_b2), the percentage of modulation of the carrier is shown in the FM/AM column.

**Jitter** - The phase deviation in the time domain.

**Weighting Filter Setup...** button - Accesses Weighting Filter Table Setup dialog. The weighting filters compensate external effects that affect the phase noise in the specified frequency ranges. When the weighting filters are applied, the trace data are corrected by the filter characteristics before the calculation of integrated noise. You must define at least 2 frequencies when using the Weighting Filter.

**Add** button - Adds a frequency below existing entries.

**Delete** button - Deletes the currently selected frequency in the table.

**Delete All** button - Deletes all frequencies in the table.

**Save Table** button - Saves the weighting filter table to a .csv file. The file should be saved in the following directory: C:\ProgramData\Keysight\Network Analyzer\WeightingFilter. All filters saved in this directory are shown on the drop down list in the Weighting Filter column.

**Load Table** button - Loads a previously saved weighting filter table.

**Select** - Selects an existing phase noise trace or allows you to add a new trace. Each
trace can have up to four defined ranges. See Displaying Phase Noise Parameters.

**Range** - Sets the integration range number.

**Type** - Sets the integration range type of the selected integration range defined as offset frequency from the carrier.

- **Off** - Disables specific range and will not be measured.
- **Full Span** - Enables the measurement bandwidth to be the full offset range defined in the Sweep tab.
- **Custom** - Enables custom-defined start and stop offset range.

**Start** - Start offset frequency for the integrated noise measurement.

**Stop** - Stop offset frequency for the integrated noise measurement.

**Weighting Filter** - Selects pre-defined weighting filter file. Select None when a weighting filter file will not be used.

**Defaults** button - Restores default phase noise settings.

**Apply** button - Applies setting changes and leaves the dialog box open to make more setting changes.

| Spot Noise Tab in dialog help | Programming Commands |
**Show Spot Noise Table** - Enable or disable displaying the Spot Noise Table below the trace display.

<table>

**Trace** - Displays trace number(s).

**Spot Frequency** columns - Displays decade edges and/or specified offset spot frequencies.

**Select Traces** - Select traces for calculating the Spot Noise.

**New Traces...** button - Add a new trace for calculating Spot Noise.

**Define Spot Frequencies** - Select the check boxes and enter specific spot frequencies to measure. A trace must be selected. If **Decade Edges** is selected, the decade edges will also be measured. Duplicate frequencies between Decade Edges and Spot Frequencies are shown only once.

**Decade Edges** - Select to measure the decade edges based on the **Start Offset** and **Stop Offset** settings defined in the Sweep tab. Deselect to measure only the defined/selected spot frequencies. A trace must be selected.

**Defaults** button - Restores default phase noise settings.

**Apply** button - Applies setting changes and leaves the dialog box open to make more setting changes.
Displaying Phase Noise Parameters

Trace Measurement Parameters

How to select and configure Measurement Parameters

Using Hardkey/SoftTab/Softkey

1. Press Trace > Trace Setup > Measure....
2. Select a parameter.

Using a mouse

1. Click Instrument.
2. Select Trace.
3. Select Measure....
4. Select a parameter.

**PN_b2** - Integrated phase noise measured at VNA input b2 (Test Port Receiver 2).
**AM_b2** - Amplitude modulation measured at VNA input b2 (Test Port Receiver 2). This parameter measures the percentage of the modulation of the carrier.

**Note:** The VNA input receiver number can be changed using the **VNA Input** function in the **RF Path** tab or by pressing **Meas > Main > VNA Input**.

**New Trace** - Add a new trace.

**Channel N** - Select a channel number for the new modulation distortion trace.

**Window N** - Select to create the new trace in an existing window or new window.

**Select All** - Select all measurement parameters.
Setting Up a Phase Noise Measurement

The following procedures describe how to set up a phase noise measurement using the Option S93031xB Phase Noise application.

In this topic:

- Hardware Setups
- Create a Phase Noise Channel
- Open the Phase Noise Setup dialog
- Set Up the Carrier
- Set Up the Measurement
- Set Up the RF Path
- Set Up the Source
- Set Up an External Source

Hardware Setups

The following are typical hardware setups for measuring the phase noise of a device. The Option S93031xB Phase Noise application is installed on the PNA/PNA-X.
Create a Phase Noise Channel
1. On the VNA front panel, press **Meas > S-Param > Meas Class...**.

2. Select **Phase Noise**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

3. In the **Confirm Measurement Class Change** dialog, click **OK** to proceed or **Cancel** to exit.

4. The **Phase Noise Setup** dialog is displayed.

5. The default Phase Noise Measurement Parameter is **PN_b2**. This means that the displayed trace is a Phase Noise measurement trace. The "b2" corresponds to the VNA receiver input to use for the phase noise measurement.

---

### Open the Phase Noise Setup dialog

1. If the Phase Noise Setup dialog is not displayed, press **Freq > Main > Phase Noise Setup...**.

2. The **Sweep**, **RF Path**, **Source**, **Spurious**, **Integrated Noise**, or **Spot Noise** tab can now be selected.
**Set Up the Carrier**

1. In the **Sweep** tab, set the **Carrier Frequency** by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This is the nominal value of the carrier frequency.

2. Set the **Carrier Threshold** by either using the up/down arrows or by double-clicking in the data entry field and entering the level using the displayed keypad. The carrier will be detected using this threshold value and will be compared to the specified Carrier Frequency. The delta indicator displays any frequency difference.

**Set Up the Measurement**

1. In the **Sweep** tab, set the **Start Offset** and **Stop Offset** by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad. This is an offset relative to the carrier frequency to position the measurement about the noise sideband to measure power density in dBc/Hz.

2. Set the **RBW Ratio** by either using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. The RBW Ratio sets the resolution bandwidth ratio, which is the specified resolution bandwidth percentage of every half decade offset frequency.

3. Set the **FFT Avg Factor** by either using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad. The average factor is multiplied by the default average count, which changes for each frequency range.

4. Select the desired **Noise Mode** using the drop down menu. Select **Fast**, **Normal**, or **Best**. The **Fast** selection has the highest noise floor and fastest measurement speed. The **Best** selection is the lowest measurement speed with lowest noise floor. Refer to the following example showing **Fast**, **Normal**, and **Best** differences:
Set Up the RF Path

1. In the RF Path tab, select the VNA Input using the drop down menu. This selects the VNA receiver input to use for the phase noise measurement. Only one can be chosen.

2. Set the Rcvr Atten using the drop down menu. This sets the VNA receiver attenuation of the selected VNA receiver.

3. Click on the RF Path Configuration... button to configure hardware paths that are available with selected PNA/PNA-X options as necessary. This ensures that the correct path has been selected for the source (for converter measurements) and receiver. Learn more.

Set Up the Source
Set up a source when the DUT requires an RF source at its input.

1. In the **Source** tab, select **ON** in the **State** column next to the desired source displayed in the list. This is the source used at the input of the DUT.

2. Set the **Frequency** for the selected source by clicking in the data entry field, clicking on the **Edit** button, then entering the frequency by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad.

3. Set the **Power** for the selected source by clicking in the data entry field, clicking on the **Edit** button, then entering the power by either using the up/down arrows or by double-clicking in the data entry field and entering the power using the displayed keypad.

4. Click on the **Power and Attenuator...** button to define and control the source power and attenuation. Learn more

5. Click on the **RF Path Configuration...** button to configure hardware components that are available with selected PNA/PNA-X options. Learn more.

---

**Set Up an External Source**

An external source can also be configured and selected as the source. Before the external source is displayed in the list it must be set up as shown in the following procedure.
1. Click on the **External Devices**... button.

2. Click on the **New** button.

3. Click in the **Name** field and type a name for the source. For example, **myMXG**.

4. For **Device Type**, select **Source**.

5. Select the **Driver**. For example, **MXG_Vector**.

6. Select **Active - Show in UI**.

7. Ensure that **Enable IO** is checked.

8. In the **I/O Configuration** field, type the VISA address of the external source.

9. Click on the **OK** button. The following is an example:

![External Device Configuration: myMXG](image)

10. The external source should be displayed in the list of sources displayed in the **Source** tab and can be selected using the Set Up the Source procedure.
Spurious Measurement

In this topic:

- Spurious Criteria
- Define a New Trace
- Setting Minimum Spurious Level
- Setting Spurious Sensibility
- Setting Omit Displayed Spur
- Displaying the Spurious Table
- Enable Spur Analysis

Spurious Criteria

The criteria used for a spurious measurement defines the threshold in terms of the standard deviation (σ) value which is calculated from the measurement result moving average.

The threshold can be set as the standard deviation (Γ) X sensibility. When the measured value exceeds the threshold, it is defined as a spur.

Define a New Trace

When the Phase Noise Measurement Class is selected and a Phase Noise channel is created, the default measurement parameter is PN_b2. This indicates that the trace is a Phase Noise measurement that will be made at the b2 receiver of the VNA. The VNA receiver can be changed using the VNA Input function in the RF Path tab. Each defined trace can have independent spurious settings.

1. In the Spurious tab, click on the Select drop down menu and select New Traces...

2. In the New Trace dialog, select PN_bN, where "N" is the VNA receiver number set using the VNA Input function in the RF Path tab.

Setting Minimum Spurious Level
If the spurious data is exceeds the minimum spurious level, it is omitted from the spurious data, or it is displayed as Power (dBc).

For example, there are two peaks (C) and (D) which are detected as a spurious in the figure below. When Power (dBc) is displayed, the peak (C) which is above the minimum spurious level turns white in color.
1. In the **Spurious** tab, click on the **Select** drop down menu and select the desired trace.

2. Set the **Min. Spur Level** by either using the up/down arrows or by double-clicking in the data entry field and entering the level using the displayed keypad.

**Setting Spurious Sensibility**

The following procedure describes how to set spurious sensibility.
1. In the Spurious tab, click on the Select drop down menu and select the desired trace.

2. Set the Spur Sensibility by either using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad.

Setting Omit Displayed Spur

This function will omit all displayed spurs.

1. In the Spurious tab, click on the Select drop down menu and select the desired trace.

2. Check Omit Displayed Spur. The following shows two spurs displayed in the top trace and, after checking Omit Displayed Spur, the bottom trace shows that the spurs are omitted.

Displaying the Spurious Table
The Spurious Table can be displayed below the trace area of the display showing Trace and Spur number, Offset frequency, Power level, and Jitter.

<table>

</tr>
</tbody>
</table>

1. In the Spurious tab, check Show Spurious Table.
2. To sort the table, click on the Table Sort Order drop down menu and select Power to sort by power or Offset to sort by offset frequency.

Enable Spur Analysis

This function enables spurious analysis search markers. See Spurious Search.

1. In the Spurious tab, click on the Select drop down menu and select the desired trace.
2. Check Enable Spur Analysis then click OK to exit the dialog.
3. On the VNA front panel, press Search > Spurious > Spurious Search. A marker is displayed over the first spur:

4. Note the frequency and level from the carrier are displayed in the top-right corner of the display.
5. To move the marker to the next spur on the right, press Spurious Right >> Search.
6. To move the marker to a spur on the left, press **Spurious Left >> Search**.

7. To place markers on all displayed spurs, press **Multi Spurious Search**.

8. To turn off all markers, press **Marker > Marker Setup > All Off**.
Integrated Noise Measurement

Integrated noise is the single sideband phase noise integrated over a measurement bandwidth from a start/stop offset frequency. Up to four offset frequency ranges can be defined.

In this topic:

- Define a New Trace
- Set Up Measurement Ranges
- Set Up Weighting Filter
- Displaying the Integrated Noise Table

Define a New Trace

When the Phase Noise Measurement Class is selected and a Phase Noise channel is created, the default measurement parameter is \( \text{PN\_b2} \). This indicates that the trace is a Phase Noise measurement that will be made at the b2 receiver of the VNA. The VNA receiver can be changed using the VNA Input function in the RF Path tab. Each defined trace can have independent settings.

1. In the Integrated Noise tab, click on the Select drop down menu and select New Traces... .
2. In the New Trace dialog, select \( \text{PN\_bN} \), where "N" is the VNA receiver number set using the VNA Input
The following procedure describes how to set up multiple measurement ranges.

1. In the Integrated Noise tab, click on the Select drop down menu and select the desired trace.

2. Click in the Type column for Range 1, click on the down arrow, then select Custom.

3. In the Start column for the range, set the frequency by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad.

4. In the Stop column for the range, set the frequency by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad.

5. Repeat steps 2 through 4 to add more ranges (up to four ranges).

6. If Weighting Filter files have been set up and saved, click in the Weighting Filter column for a range, click on the down arrow, then select the file. See below for a procedure on how to set up a Weighting Filter file.
The weighting filter allows weighting values to be entered at specified frequencies. The weighting filters compensate external effects that affect the phase noise in the specified frequency ranges. When the weighting filters are applied, the trace data are corrected by the filter characteristics before the calculation of integrated noise.

1. In the Integrated Noise tab, click on the Weighting Filter Setup... button.

2. Click on the Add button.

3. In the Frequency column, set the frequency by either using the up/down arrows or by double-clicking in the data entry field and entering the frequency using the displayed keypad.

4. In the Weighting Value column, set the value by either using the up/down arrows or by double-clicking in the data entry field and entering the value using the displayed keypad.

5. Repeat steps 2 through 4 to add more weighting values.

6. Click on the Save Table button to save the settings to a file (.csv).

Displaying the Integrated Noise Table

The Integrated Noise Table can be displayed below the trace area of the display showing trace number, start/stop offset, weighting filename (if used) integrated noise, phase modulation measured in degrees and radians, residual FM (Hz) or residual AM (%), and jitter. Residual FM (Hz) will be displayed when the PN_b2 Phase Noise measurement parameter is selected; residual AM (%) will be displayed when the AM_b2 Phase Noise measurement parameter is selected.
1. In the Integrated Noise tab, check Show Integrated Noise Table.
Spot Noise Measurement

Spot Noise measurement are measurements made at specific frequencies. The measurements can be made at each decade, determined by the start/stop offset frequencies, up to six defined frequencies, or a combination of both decade and defined frequencies.

In this topic:

- Define a New Trace
- Define Spot Frequencies
- Displaying the Spot Noise Table

Define a New Trace

When the Phase Noise Measurement Class is selected and a Phase Noise channel is created, the default measurement parameter is PN_b2. This indicates that the trace is a Phase Noise measurement that will be made at the b2 receiver of the VNA. The VNA receiver can be changed using the VNA Input function in the RF Path tab. Each defined trace can have independent settings.

1. In the Spot Noise tab, click on the New Traces... button.
2. In the New Trace dialog, select PN_bN, where "N" is the VNA receiver number set using the VNA Input function in the RF Path tab.
Define Spot Frequencies

The following procedure describes how to define measurements at specific frequencies and/or at the decade edges. The decade edges are determined by the Start Offset and Stop Offset settings in the Sweep tab.

1. In the Spot Noise tab, select the desired trace displayed under Select Traces.

2. To measure phase noise at each decade, check Decade Edges and leave the other spot frequencies unchecked.

3. To define specific frequencies to measure other than at the decade edges, perform the following steps:
   a. Uncheck the Decade Edges check box.
   b. In the data entry field, set the spot frequency to measure (up to six) by either using its up/down arrows or by double-clicking in its data entry field and entering the frequency using the displayed keypad.
   c. Check the corresponding box to enable the measurement at this specific frequency.
   d. Repeat steps a through c for each frequency to measure.

Displaying the Spot Noise Table
The Spot Noise Table can be displayed below the trace area of the display showing the trace number and corresponding measurement frequencies and the phase noise in dBc/Hz.

<table>
<thead>
<tr>
<th>Trace</th>
<th>10 Hz</th>

<td>-121.16 dBc/Hz</td>
<td>-136.44 dBc/Hz</td>
<td>-133.20 dBc/Hz</td>
</tr>
</tbody>
</table>

1. In the **Spot Noise** tab, check **Show Spot Noise Table**.
AM Noise Measurement

Noise that modulates the phase of the carrier is referred to as amplitude modulation of the carrier. The following procedure describes how to measure AM Noise.

1. Set up a Phase Noise measurement as described in Setting Up a Phase Measurement.

2. On the VNA front panel, press Meas > Main > AM_b2. The b2 is the VNA input and could be different depending on the hardware configuration.

3. To create a new AM Noise trace, press Meas > Main > Other. The Measure dialog is displayed:

4. In the Measure dialog, check AM_b2 AM Noise.

5. In the Measure dialog, check New Trace then select the desired Channel and Window.

6. The following example displays an AM measurement at the b4 VNA input:
7. The FM/AM column displays the percentage of modulation of the carrier.
The Spectrum Analyzer function is available with Sx090A/B.

Spectrum Analyzer mmWave Measurements

Noise Power Ratio (NPR) Measurement

Other VNA Applications

Features, Requirements, and Limitations

Features

- General purpose spectrum analysis for component measurements
- Add multi-channel spectrum analysis (multiple receivers/frequencies)
- Perform fast spurious search in broad frequency band
- Enable spectrum analysis at calibration plane using VNA calibration and Fixturing (de-embedding)
- Single-connection, multiple measurements
- Internal, manual, and external triggering - learn more
- Marker -> SA available in Standard, SMC, and Swept IMD channels
- Gating - learn more
- Coherence Image Rejection for multi-tones and repetitive test signals
- Export data
- All VNA are supported.
- Broadband and Banded millimeter-wave systems are supported - learn more
- External DC meter configuration is supported for a SA measurement channel.

Requirements

- Spectrum Analyzer Option S930900A/B.
- Windows 7 or Windows 10 operating system
- Option S930909A/B (10 MHz to = 90 GHz) for broadband spectrum analyzer millimeter-wave measurements
- Option S93093A/B (10 MHz to = 120 GHz) for broadband spectrum analyzer millimeter-wave measurements
- Option S93094A/B (> 110 GHz) for banded spectrum analyzer millimeter-wave measurements
- IF Response Adjustment required after installing Option S93090xA/B, S93093A, or S93094A/B

Limitations

- For PNA-L 4-port models, only one reference receiver can be used at a time
For PNA-L models, millimeter-wave measurements are not available

**Specificities versus legacy Spectrum Analyzer setups**

This Spectrum Analyzer application works on VNA hardware:

- There is no hardware pre-selector filter (it used to be a slow Yig filter in legacy Spectrum analyzer hardware).
- The IF bandwidth is limited by hardware design to 30 MHz (can be increased with advanced settings to 38 MHz). This is because PNA ADCs are baseband running at 100 MHz.
- Image rejection in IF band is not based on hardware filtering but on software comparison of different acquisitions of the same RF frequencies with different analyzer internal LOs.

This has some consequences:

- Sweep time is very fast for low resolution bandwidth compared to legacy spectrum analyzers (they have to wait for Yig filter stabilization).
- Real time wideband signals can only be accurately acquired if they fit in the instantaneous IF bandwidth: 30 MHz. Real communication signal or random noise signals can then be measured with no Image rejection mode (None, LO Low or None, LO High Image Reject Type).
- Repetitive wideband test signals can be measured accurately if the RBW is set low enough, or if the Coherent mode is enabled. Then, any signal bandwidth is possible, up to several GHz wide. If the coherent mode is not possible, then we recommend to set the RBW equal or lower to 1/10 of 1/signal repetition rate. Example: for a 1 ms repetitive test signal, set the RBW to 100 Hz or lower.

**Note:** The wideband repetitive test signal case is a very important and common one, as a VNA is a component test tool, not a signal analysis tool. NPR, and ACPR measurements of active devices can be performed accurately with this Spectrum Analyzer Application.

**SA Setup Overview**

2. Set up the SA source frequency and power.
3. Define the measurement parameters.
4. Select markers.
5. Calibrate the SA channel using the Cal All wizard.

**How to make SA Measurements**
Create a Spectrum Analysis Channel

1. On the VNA front panel, press Meas > S-Param > Meas Class... .

2. Select Spectrum Analysis, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.

3. A Spectrum Analysis measurement is displayed.

Configure SA settings

Using Hardkey / SoftTab / Softkey

1. Press Freq > Main > SA Setup... .

Using a mouse

1. Click Stimulus
2. Select SA Setup...

SA Setup Dialog tab help
**Sweep Type** - Sets the spectrum analysis sweep type. See Type (Sweep).

**X-Axis Point Spacing** - Enables or disables the separate segment sweeps in a Dual-Band Configuration for frequency conversion measurements. The span increases to display input and output signals.

**Show segments** - Displays the segment table at the bottom of the display. Number of points for each segment cannot be specified.

**Hide segments** - Hides the segment table.

**Processing**

**Resolution Bandwidth** - Provides the ability to resolve, or see closely spaced signals. The narrower (lower) the Resolution Bandwidth, the better the spectrum analyzer can resolve signals. In addition, as the Resolution Bandwidth is narrowed, less noise is measured by the spectrum analyzer ADC and the noise floor on the display lowers as a result. This allows low level signals to be seen and measured. However, as the Resolution Bandwidth is narrowed, the sweep speed becomes slower.

**Auto** - Check to couple Resolution Bandwidth to the frequency span in a ratio based on the Span/RBW setting. As the frequency span is narrowed, the Resolution Bandwidth is also narrowed providing increased ability to resolve signals. Clear to uncouple the settings.

**Video Bandwidth** - Sets the video averaging factor. The averaging operation is applied after the DFT (Discrete Fourier Transform) and before the image rejection. The trace data is smoothed with the method selected by the Video Averaging Type. More smoothing occurs as the Video BW is set lower. However, as the Video BW is narrowed, the sweep speed becomes slower. The Video Bandwidth can be set from 3 Hz to 3 MHz when Auto is deselected.

**Auto** - Check to couple the Resolution Bandwidth to the Video Bandwidth in a ratio based on the RBW/VBW setting. Clear to uncouple the settings.

**Detector Type** - A "detector" is an algorithm used to map DFT bins into display buckets. There are typically several DFT bins in a single display bucket, and the detector determines how to translate the multiple DFT values into a single display value.

**Peak** - Displays the maximum value of all the measurements in each bucket. This setting ensures that no signal is missed. However, it is not a good representation of the random noise in each bucket.

**Average** - Displays the Root Mean Squared (RMS) average power of all the measurements in each bucket. This is the preferred method when making power measurements.
**Sample** - Displays the center measurement of all the measurements in each bucket. This setting gives a good representation of the random noise in each bucket. However, it does not ensure that all signals are represented.

**Normal** - Provides a better visual display of random noise than Positive peak and avoids the missed-signal problem of the Sample Mode. Should the signal both rise and fall within the bucket interval, then the algorithm classifies the signal as noise. An odd-numbered data point displays the maximum value encountered during its bucket. An even-numbered data point displays the minimum value encountered during its bucket. If the signal is NOT classified as noise (does NOT rise and fall) then Normal is equivalent to Positive Peak.

**NegPeak** - Displays the minimum value of all the measurements in each bucket.

**Peak Sample** - Attempts to determine if the display bucket contains an actual signal, or just noise. If a signal is present, the Peak detector is used, otherwise Sample is applied.

**Peak Average** - Attempts to determine if the display bucket contains an actual signal, or just noise. If a signal is present, the Peak detector is used, otherwise Average is applied.

**Bypass** - Check to bypass the Detector Type to view all display points from the DFT. This is only available if the total number of DFT points can be handled by the display.

**Video Averaging Type** - Determines how to compute the video average. When Auto is selected, the optimum type of averaging for the current instrument measurement settings is selected. It averages the magnitude of the DFT bins. Averaging only applies if the video bandwidth is less than the resolution bandwidth.

**Voltage** - Selects averaging of the detected signal's magnitude and returns the result.

**Power** - Selects averaging of the detected signal's squared magnitude and returns the square root of the result.

**Log** - Selects averaging of the detected signal's natural logarithm of the magnitude and returns the exponentiated value of the result.

**Voltage Max** - Returns the maximum voltage (signal magnitude) measured during the averaging period.

**Voltage Min** - Returns the minimum voltage (signal magnitude) measured during the averaging period.

**Averaging Count** - Reads the number of Video bandwidth sweeps that are averaged together. This readout is displayed to the right of the **Averaging Type** selection (the small "1" shown in
the dialog above). It can be read with the remote interface using the SENS:SA:BAND:VID:AVER:COUNt? command.

**Settings**

Sets the SA (receiver) frequency range when running Linear Frequency sweep type. Use either of the following pairs of settings to determine the frequency range.

**Start /Stop** - Specifies the beginning and end frequency of the swept receiver range. Start is the beginning of the X-axis and Stop is the end of the X-axis. When the Start and Stop frequencies are entered, then the X-axis annotation on the screen shows the Start and Stop frequencies.

**Center /Span** - Specifies the value at the center and frequency range. The Center frequency is at the exact center of the X-axis. The Frequency Span places half of the frequency range on either side of center. When the Center and Frequency Span values are entered, then the X-axis annotation on the screen shows the Center and Span frequencies.

**Number of Points** - Selects the number of trace points on the display. When the Detector is bypassed, the number of display points is read only, it shows the current DFT points to cover the RF span.

*Note:* When running Segments, the frequency ranges are set by the segment table.

**Attenuators**

Receiver Attenuation is used to protect the test port receivers from damage or compression. Receiver attenuation causes the applied power at the receiver to be less than the power at the test port by the specified amount of attenuation.

Receiver Attenuators are offered as an option. Learn more.

Type or select independent attenuation values for each test port receiver.

A preference can be set to mathematically offset (or NOT) the reported power at the test port receivers by the amount of receiver attenuation. By default, All VNA models offset the display. Learn how to set the preference.
**Power On (All Channels)** Check to enable source power for all channels. Only turns power ON if the port State setting is ON.

**Port Powers Coupled**

- **Coupled** (checked) The power levels are the same at each test port. Set power at any test port and all test ports change to the same power level.

- **Uncoupled** (cleared) The power levels are set independently for each test port. Uncouple power, for example, if you want to measure the gain and reverse-isolation of a high-gain amplifier. The power required for the input port of the amplifier is much lower than the power required for the output port. A power sweep can also be performed with uncoupled power. Learn more about Setting Independent Port Power.

**Source Cells**

**Name** - Lists the test ports through which an internal source is available. If an external source has been configured, it will appear at the bottom of the list.

**State**

- **ON** Source power is ALWAYS ON. Only one port can be turn on unless the unit has the second source. Learn about internal second source restrictions.
- **OFF** Source power is never ON, regardless of the measurement requirements. Use this setting to prevent damage to a sensitive DUT test port.

- **No Control** Available ONLY on external sources. The SA application will NOT control the external source.

**Type (Sweep)**

- **CW** - The source is set to a CW frequency.

- **LinFreq** - The source is set to sweep from the Start to Stop frequency.

- **Power** - The source is set to a power sweep.

- **Phase** - The source is set to a phase sweep.

- **LinF+Pwr, Freq+Pha, Pow+Pha, Fr+Pw+Ph** - Multi-parameter sweep for the specified parameters. Set the range of sweep for each parameter.

**Frequency** - Click in the cell, then click **Edit**, to start the Frequency Settings dialog (below).

**Power** - Sets the power level at the output of the source. Click in the cell, then click **Edit**, to start the Power Settings dialog (below).

**Phase** - Control source phase of a VNA source or external source. Learn more.

**Pulse** - Enable/disable pulse measurements. Learn more.

**IQMod.** - Modulated I/Q file. Clicking Edit accesses a dialog for setting up an I/Q modulated file that is sent to a source for measuring Noise Power Ratio (NPR). Refer to the Noise Power Ratio (NPR) Settings topic for descriptions of the modulation dialogs.

**RF source sweep order**

- **Frequency Power Phase** - Sweep from Start to Stop frequency first then sweep power then sweep phase.

- **Power Frequency Phase** - Sweep power first then sweep from Start to Stop frequency then sweep phase.

- **Phase Frequency Power** - Sweep phase first then sweep from Start to Stop frequency then sweep power.

- **Phase Power Frequency** - Sweep phase first then sweep power then sweep from Start to Stop frequency.

- **Frequency Phase Power** - Sweep from Start to Stop frequency first then sweep phase then sweep power.
power.

Power Phase Frequency - Sweep power first then sweep phase then sweep from Start to Stop frequency.

**Path Configuration**  Learn more

**Power and Attenuator**  Learn more

**External Devices**  Learn more

---

**Multitone**

The set of Multitone properties enable an enhanced Image Rejection mode that takes benefits of the stimulus test signal knowledge.

If the stimulus test signal is repetitive with a repetition rate of $x$ seconds, it only contains tones that are on a $1/x$ frequency grid. Example: if the test signal out of an arbitrary wave generator repeats every 1 ms, then it only contains frequencies on a 1 kHz grid (noise is not considered here). We will take this into account here to make the PNA-SA DFT analysis grid landing exactly on the same grid.
Moreover we will use the test signal knowledge to adjust the PNA-SA LO frequencies in order to avoid having 2 tones from the multitone stimulus signal landing at the same location at the PNA IF side. This makes the image rejection process deterministic.

**Enable multitone image rejection**

- **Enabled** (checked) The other parameters of the Multitone dialog are taken into account. Enabling this mode will set the DFT mode to arbitrary, the RBW shape to No Window, the RBW grid to a set of suitable values, and the list of analysis LOs accordingly. This setting is not compatible with the advanced settings “Force ADC record size” or “Force LO to frequency”.

- **Disabled** (cleared) Legacy stochastic image rejection mode of the PNA-SA application. When disabled, the window type is set back to what it was before enabling, and the RBW list is also set to the previous setting.

**Tone Spacing** - The tone spacing of the multitone signal (Hz).

**Waveform Period** – 1 over the tone spacing. This is the test signal repetition rate (seconds).

**Reference Tone** – If the multitone grid does not start from 0 Hz, its offset is set here. To make this more convenient, this dialog accepts as well the frequency of any tone of the multitone grid (Hz).

**Reject up to harmonic** – Set the number of test signal harmonics you want to be protected against. This adds constraints to the list of LOs used to cover the span.

**Nyquist protect order** – Enhancement for the deterministic coherent image reject mode. It ensures the Nyquist images of the signal tones in the IF bandwidth are not falling back on top of real signal frequencies. To be able to enable Nyquist protection, the tone spacing of the coherent signal cannot be an integer divider of the ADC sampling clock (100MHz for a PNA). Enabling this option often results in a larger ADC recordsize (or a smaller DFT tone spacing) at SA receiver side.

**Vector Averaging** - Average ADC samples by the specified number (=1) in FPGA memory before the DFT processing. For example, if an ADC record size of 1,000 samples is acquired and Vector Averaging is set to 2, then 1,000 samples will be averaged to 1,000 samples and the result (1,000 samples) will be stored in FPGA memory. In other words, we acquire 2,000 samples form ADCs and send 1,000 averaged samples to the next processing stage. Vector averaging helps to reduce noise and increase dynamic range. However, this feature should only be used when the stimulus frequencies are known and coherent with the current ADC record size. A value of 1 means no averaging. Note this feature behaves like ADC Stacking+1. The maximum vector averaging value is 65536 or below. It depends on the RBW and the decimation.
Check box- Check to enable the ADC sample Vector Averaging to be specified manually.

**Note:** Vector Averaging and Video Bandwidth averaging cannot be set together. When enabling vector averaging, if the coherent mode is enabled then Video Bandwidth is turned off. The ADC Record Size x Vector Averaging must be = 64 Mega Samples (or = 32 Mega for some multiple receivers configurations).

**Note:** Vector Averaging is a great averaging method when Coherent Multitone mode is enabled. We recommend increasing it in Coherent Multitone mode instead of reducing the RBW to reduce the noise floor.

**Note:** Coherent mode (and Vector Averaging too) will work well if and only if the signal source and the PNA have their reference clocks synchronized. This is usually done by connecting a 10 MHz reference BNC cable between the signal source and the PNA.

**Note:** Vector Averaging is also known as Stacking. In fact, Vector Averaging = stacking +1.

**Data Display**

- **Show All** - Legacy behavior, shows the noise or the spurious between the tones. Note the RBW shape for multitones (No Window) makes the noise or the out of grid spurious amplitude values not accurate.

- **Zero the non-tones** - All the span frequencies that are not on the multitone grid have their amplitudes set to -200 dBm before correction. This makes band power marker measuring only the power for multitone frequencies, and not the noise power.

- **Discard the non-tones** - Deletes span frequencies that are not on the multitone grid.

**Multitone settings are valid** - Displays status of multitone settings.

**Tone Phases and Phase Stitching**

**Compute Phases** - Check to enable phase computation.

**Display Phases if Tone Power >** - Set the phase display minimum level.
ADC Triggering

**Advanced Trigger Mode** - Check to enable a measurement trigger based on the ADC Level or a period of time.

**ADC Level** - Initiate a measurement trigger event whenever the ADC level of any of the receivers at work is greater than this specified value (0 = ADC Level = 1683). A level of 100 is recommended as a default value. The ADC level is an uncalibrated value that reflects signal peak amplitude. It will detect RF energy only within the current IF bandwidth, so it would make sense to use this feature associated with a Forced LO value or a narrow SA span.

**Periodic Counter** - Initiate a measurement trigger event based on the specified period. For example, if **Periodic Counter** is set to 1,000,000, then an acquisition occurs every 0.01 sec (1,000,000 x ADC Sampling Frequency (10 nsec)).

**Trigger...** - Accesses the Trigger dialog for setting up triggering.

**Hold** - The channel accepts NO trigger signals.

**Single** - The channel accepts ONE trigger signal, then goes into Hold.

**Continuous** - The channel accepts an infinite number of trigger signals.

**Pulse Measurements**
Off - Turns pulse off.

Standard Pulse - Turns pulse on.

Duty cycle - Displays the duty cycle relative to the current settings for Pulse Period and Pulse Width (Pulse Width/Pulse Period).

Meas. Width - Sets the time the measurement pulse is on.

Pulse Period pulldown - Allows the selection of the following:

- **Pulse Period** - The time to make one complete pulse.
- **Pulse Frequency** - The reciprocal of Period (1/ Period).
- **Pulse Duty Cycle** - **Pulse Width** divided by the **Pulse Period**.

RF Pulse Width - Sets the width of the RF Source pulse.

One LO Acquire - The ADC acquisition time required to measure the data for a single FFT.

Full Sweep - Complete cycle time of measurement including background sweeps.

Pulses per LO - Number of pulses which will occur during the sweep for each LO.

Pulse Details

Name - Pulse generator outputs in numerical order.

Device - Indicates the device being controlled by the pulse generator output.

- **Pulse0** - Always set to **Receiver**. Sets the amount of time to wait before triggering the ADC to begin acquisition and is always selected for Pulse0 and cannot be changed. Pulse0 adds (ADC Delay) + (Modulator Delay). The ADC will begin measuring data 250 ns before the rising edge of Pulse0. This delay is indicated in the **Fixed ADC Delay = 250 ns** annotation.

- **Pulse1** through **Pulse4** - Pulse outputs can be set to the following:

  - **RF Src** - Selecting **RF Src** indicates that the pulse signal is used to drive the RF modulator. Only one pulse generator output can be used to drive an RF source. If you try to set more than one pulse generator output to **RF Src**, then the other one will be set to **User N** (where "N" is the pulse generator number).

  - **User 1, User 2, User 3, User 4** - Labels for user convenience. These labels do not connect the pulse generator to any specific hardware. These selections may be used to control a DUT, DC biases, or other signals.
- **Activity** - This selection outputs a signal on Pulse4 when the ADC is active. This is the same as Pulse4 Output Indicates ADC Activity on the Pulse Generators Setup dialog. If ADC is selected for Pulse4, then the pulse width and delay entries are grayed out because Pulse4 is no longer a pulse output.

**Width** - RF Source pulse width. This setting is the same as **Pulse Width** under RF Pulse.

**Meas Delay** - Sets the time before each pulse begins.

**Width Adjust** - Adjusts the measurement pulse width.

**Invert** - Check to cause the pulse ON time to be active low and OFF to be active high.

**Enable** - Check to enable individual pulse generators.

**Plot Pulse Timing...** - Accesses Pulse Timing display to evaluate the pulse timing setup.

**Pulse Generators...** - Accesses the Pulse Generator Setup dialog for setting up pulse measurements.

---

### Advanced Settings Dialog tab help

![Advanced Settings Dialog](image)

**Properties**

![Properties](image)
**RBW Shape** - Selects the digital filter (window) to apply to the time domain IF signal. The filter effectively "shapes" the signal before application of the DFT to help avoid discontinuities which add unwanted frequency content to the spectrum. Each filter has its own advantages and disadvantages.

**Gaussian** - Selects a Gaussian window. The Gaussian window has good frequency separation and moderate amplitude accuracy. This window provides higher dynamic range because it has much lower side lobes. It is used for general-purpose measurements and when high dynamic range is required.

**Flat Top** - Selects the flat top window for amplitude measurement of sinusoidal frequency components. The flat top window has moderate frequency separation and excellent amplitude accuracy. It is typically used for narrowband signals when measuring the amplitude of a particular frequency component with greater amplitude accuracy.

**Kaiser** - Selects the Kaiser window which is an approximation of a Slepian window using Bessel functions. This window has a relatively high dynamic range and is similar to the Blackman window.

**Blackman** - Selects the Blackman window. This window has a relatively high dynamic range and is similar to the Kaiser window.

**No Window** - The No Window selection does not modify the time-domain data in any way before applying the DFT. This selection is very fast but may yield a significant number of side lobes in the frequency domain because of spectral leakage. This selection has a rectangular shape and does not attenuate any portion of the time record.

**Image Reject Type** - Sets the minimum number of distinct DFT acquisitions to use when computing an actual signal. As the number of DFT acquisitions increases from the None, LO Low setting to the Max setting, an increased number of erroneous signals are eliminated. Therefore, the Better and Max settings provide the highest confidence that what remains are actual signals, at the expense of slower measurements.

**None, LO High** - Selects 1 acquisition with the LO higher than the receiver frequency.

*Note: Selecting None, LO High with full span is not possible. See SA Warning Messages.*

**None, LO Low** - Selects 1 acquisition with the LO lower than the receiver frequency.

*Note: Selecting None, LO Low with full span is not possible. See SA Warning Messages.*

**Min** - Selects 2 acquisitions.

**Min, LO High** - Selects 2 acquisitions (like Min) and both acquisitions consider that the LO
is higher than the receiver frequency.

**Min, LO Low** - Selects 2 acquisitions (like Min) and both acquisitions consider that the LO is lower than the receiver frequency.

**Normal** - Selects 4 acquisitions.

**Better** - Selects 6 acquisitions.

**Max** - Selects 8 acquisitions.

**Image Reject Strength** - Sets the image rejection strength. During the image rejection process, several LO acquisitions overlap at the same RF frequency (depending on the Image Reject Type). As a result, different RF signal values can be returned. This feature sets the acceptable power differences between measurements performed with different LOs in determining actual signals. Possible values are Weak, Normal, Strong. Weak accepts more difference between measurements, and strong less difference.

**RBW/VBW** - Sets the ratio of Resolution Bandwidth to Video Bandwidth when the Video Bandwidth is in Auto mode.

**Span/RBW** - Sets the ratio of Span to Resolution Bandwidth when the Resolution Bandwidth is in Auto mode.

**CF Step Size** - Manually sets the amount Center frequency change that occurs when $\Delta f$ is clicked (next to the value).

- **Auto** - Each press of the $\uparrow\downarrow$ arrows increments or decrements the Center frequency by 5% of the current frequency span.

**Occupied BW search min** - Sets the minimum search frequency to use during an Occupied BW search measurement. Power below this frequency is ignored. See Occupied BW Ratio for information about setting up this measurement type.

**DC Sources**

DC source control allows the spectrum to be measured at multiple DC source settings.

**Enable DC Outputs** - Enables all DC source outputs that are turned ON in the DC Source dialog. This same selection is found in the DC Source Dialog.

**Enable DC Sweep** - Enables the DC sources to sweep between their start and stop voltages. If not selected, then the DC sources will be set to their start voltages.

**Number of DC levels** - Defines the number of voltage levels in the DC sweep.

The following settings apply to the measurement loop order. The SA may be programmed to loop through a series of spectrum measurements at multiple RF source frequencies,
multiple RF source powers, and multiple DC voltages. These radio buttons determine whether the DC sources are swept before the RF power and frequencies are swept, or whether the DC sources are swept after the RF power and frequencies are swept.

**Sweep Order**

**DC before RF** - Sweep through each DC voltage step first then sweep through the next frequency.

**RF before DC** - Sweep through each frequency step first then sweep through the next DC voltage.

**External Devices...** button - Learn more.

**DC Sources...** - Configure internal DC sources. Learn more.

**Dual-Band Configuration**

The dual band configuration adds support for frequency conversion measurements. The following shows a down-converter measuring lower and upper ACPR and NPR. For this example, the RF input is 3.1 GHz on Port 1 from an N5182A MXG, the mixer IF output is 2.2 GHz on Port 2, and the mixer LO input connected to Port 4 is 900 MHz.

**Note:** The frequency conversion measurements also supports power sweep types to sweep from a start to a stop power.

![Dual-Band Configuration Diagram]

**Enable segments auto configuration** - Automatically configures separate segment sweeps to display both input and output signals regardless of the frequency separation. In the above down-
converter example, the segment sweep for the output (signal on the left) was set to 2.04 GHz to 2.36 GHz while the input segment sweep (signal on the right) was set to 2.94 GHz to 3.26 GHz. This was configured automatically when the check box is checked.

**Band** - Displays the band numbers corresponding to the input and output.

**Source** - Selects RF signal source from the pull down menu.

**Port** - Selects the port number to assign to the input and output.

**Center** - Sets the center frequency of each band.

**Inverted** - Inverts markers if necessary to position the NPR marker in the notch.

**Band 2 center offset** - LO offset value.

**Embedded LO**

**Enable Embedded LO** - Check to enable measurements of mixers that have a fixed LO inside the DUT.

*Note:* Embedded LO does not support signals with a tone spacing of less than 1 kHz.

**Setup...** - Opens the Embedded LO dialog.
Enable Embedded LO - Check to enable measurements of mixers that have a fixed LO inside the DUT.

Tuning Method - These settings determine the amount of time spent versus the degree of accuracy to which the LO Frequency is measured. Accuracy is compromised when noise starts to appear on the measurement trace.

Broadband and Precise  Does the entire tuning process for each background sweep.

Precise Only  Does NOT perform broadband tuning on each sweep. Use this setting when the embedded LO is stable. The signal (after broadband) must be within ½ the tuning IFBW. If the signal will always be within ½ the IFBW, broadband tuning is not needed. Most satellite components are within 3 kHz absolute so might not need broadband tuning.

Disable Tuning  Only the previously measured LO Frequency Delta is applied to the reference mixer LO and VNA receivers.

Tune every - Set the interval at which tuning is performed before a measurement
sweep. 'Tune every 3 sweeps' means that every third measurement sweep is preceded by tuning sweeps. If the embedded LO drifts, or if regularly changing DUTs, use 'Tune every 1 sweep'.

**Broadband Search** - Set the frequency span over which to measure the embedded LO frequency.

**Noise BW** - Noise Bandwidth used for Broadband and Precise tuning sweeps. This sets the resolution in the Broadband sweeps.

**Max Iterations** - The maximum number of Precise sweeps to make. When this number is reached, the final measurement is used.

**Tolerance** - When two consecutive Precise measurements are made within this value, the final measurement is used. If this is not achieved within the Max Iterations value, then the last measurement is used. This is the best of the 'Tunings settings' to change to improve accuracy.

**LO Frequency Delta** - The absolute difference between the measured embedded LO frequency and the LO setting that is entered in the Mixer Tab dialog.

**Find Now** - The VNA finds and measures the actual LO frequency using the current dialog settings. This data is displayed in the Status box.

**Default** - Resets the LO Frequency Delta and Tuning parameters to their default settings.

**Advanced >> button** - Accesses the IF, Processing, ADC & LO, and Data dialogs.
IF Gain

**Auto** - Selects the appropriate amount for gain versus RF frequency bands for each receiver IF Path.

Or select a specific amount of gain (in dB) for IF receiver paths.

**Couple all IF paths** - When checked, all receivers assume the same setting. When cleared, each receiver can assume an individual setting.

**IFConfig** - Accesses the IF Path Configuration dialog. Learn all about IF Path Configuration.

IF Bandwidth

**ADC Filter** - Selects between a narrow and wide IF filter anti-aliasing path.

- **Narrow 11MHz** - Selects the ADC 11 MHz IF filter path. A warning message will appear if the Narrow IF filter path is selected and the Resolution Bandwidth is > 1 MHz. See SA Warning Messages.

- **Wide 38MHz** - Selects the ADC 38 MHz IF filter path.

**Auto** - Check to automatically set the ADC Filter setting based on the ADC Sampling Frequency.

**DFT Bandwidth Auto** - Enables the default values for DFT bandwidth.
With **Auto** checked, the default values are:

**Narrow** - 1 MHz to 10 MHz

**Wide** - 1 MHz to 34 MHz

With **Auto** unchecked, the values can be entered manually. The ranges are:

**Narrow** - 500 kHz to 11 MHz

**Wide** - 500 kHz to 44 MHz

---

**DFT Type** - Sets the DFT record size type. The types include:

- **Power of 2** - Sets the DFT record size to the next power of 2 greater than or equal to the current ADC record size. This is the fastest DFT processing available; the power of 2 record size allows for very efficient computation shortcuts (also known as the FFT algorithm).

- **Fastest** - Sets the DFT record size as close as possible to the ADC record size (larger or equal) while optimizing processing speed.

- **Optimized Radix** - Sets the DFT record size to the minimum integer number larger or equal than the ADC record size that can be decomposed with 2,3,5,7,11,13
radixes (also known as the 13-smooth numbers). The Intel CPUs have shared-coded trigonometric values for 2, 3, 5, 7, 11, 13 fractional angles; the DFT code takes benefits from that for efficient DFT processing.

**Arbitrary** - Sets DFT record size equal to the ADC record size. If the current ADC record size is a large prime number, then the DFT can be very slow. Sometimes, the record size will be increased more than the minimum number required to match the 13-smooth condition, if the whole processing of the sweep is faster with a record size that has a faster DFT time. There is a trade-off here: increasing the record size to speed up the DFT will increase the amount of data to process for the further steps of the SA processing (image rejection, detection).

**Additional comments:**

There is a given ADC record size that gives a given RBW (for a given window type), the RBW evolves as 1/ADC record size. If the DFT record size must be greater, depending on the DFT mode, some zeros will be added to the ADC record size. This is the difference that can be noted between the ADC record size and the DFT record size on the Advanced Processing dialog.

When running the coherent mode of SA, the Arbitrary mode will always be selected, to make sure the DFT bins frequencies exactly land on the coherent signal tones.

The Power of 2, Optimized Radix, and Fastest mode have the same behavior regarding the RBW setting: These 3 modes are increasing the ADC record size to the next best match. This is more sensitive with Power of 2 mode, as the density of available ADC record size is sparse.

The Power of 2 mode makes the SA computation behave exactly like some tools based on FFT processing; this is a use case of this mode. The other use case is to get the fastest processing time that can be useful for intensive spurious search measurements. The penalty is the small number of RBW values available.

The Optimized Radix mode is currently the default mode, this is the one that gives the most accurate RBW setting. The Fastest is to be tried if speed matters for a given non-coherent SA setting.

For example: running 100 kHz RBW with Gaussian filter, the ADC record size must be 1988 samples. Here are the DFT lengths for the different algorithms:

- Power of 2: 2048
- Fastest: 2048
- Optimized Radix: 2000
- Arbitrary: 1988

**End of Sweep Processing**

The End of Sweep Processing function is used to keep the memory buffer of the last full sweep in memory for further processing. This is not done by default because keeping the whole data in memory requires large
amounts of memory and processing (for example, in the case of wide span or low RBW).

Before the implementation of this function, raw data could be sent to a file (ascii or binary) or the fifo, as this can be done while sweeping with no need to keep the whole data in memory. This option is still available.

With each sweep, the data buffers are filled, and are erased if a new speed is started. In other words, this feature works well in the logic of “Single” sweep. You must ensure that a full sweep is in the buffers before pulling out raw data.

**Receivers** - The receiver list can be either ALL, or a specific valid receiver. Only the receivers currently defined for measurement traces can be kept in memory.

**Keep whole sweep data** - Check to keep last full sweep data in memory.

**Info**

**Acq. Time for 1 LO** - Displays the LO acquisition time which is the ADC Record Size x ADC Sampling Frequency (10 nsec or 40 nsec) x (1 + Stacking) x (Video Averaging Coefficient). When settings affecting this value are changed, the displayed value is not updated automatically and will become grayed out. To update the value, close then open this dialog. The analyzer must be sweeping to update values.

**Span Acq. Time** - Displays the total acquisition time to perform a SA sweep. For simple cases, it is the acquisition time of one LO multiplied by the number of LOs. When running Multiple recording coherent pulse mode, the acquisition time here takes into account the duty cycle of the pulses.

**Span LOs count** - Displays the number of LO acquisitions determined by the Image Reject selection and the span. When settings affecting this value are changed, the displayed value is not updated automatically and will become grayed out. To update the value, close then open this dialog. The analyzer must be sweeping to update values.

**Span bins count** - Displays the current span DFT bin count, the number of DFT points processed across the total RF span. When the Detector is bypassed, this is the number of points that are sent to the display.

**DFT resolution** - Displays the DFT resolution.

**DFT record size** - Displays the current DFT record size.

**ADC record size** - Displays the ADC record size value.

**ADC with average** - Displays the ADC acquisition time of one LO multiplied by the averaging (vector averaging or video averaging) factor. It is the straight ADC acquisition time that has to go into the ADC memory for further processing.

**ADC frequency** - Displays the ADC frequency.
**Coherence ratio** - Displays the coherence ratio value.

**Display image reject traces** - Check to display the data acquired by each LO. The minimum number of meaningful traces is determined by the "Image Reject" setting (described in the Advanced dialog above).

**About Image Reject Traces**

These traces display the spectral content of the measured signal for each LO frequency used in the acquisition. The number of ImageReject traces you want to look at is tied to the 'Image Reject' setting. For example, 'Normal' setting is at least 4 ImageReject traces, and 5 more generally.

This function is intended to be used as a diagnostic tool if something looks suspicious.

**Note**: Mixer calibration and user calibration are not applied to the image rejection traces, thus the amplitude readout value is not accurate.

**About Acquisition Time and Sweep Time**

The Acquisition time for 1 LO is really the duration of the ADC acquisition run for one LO setting. Depending on the SA span and the image rejection mode, the number of LOs required for a given SA frequency span changes. This number is reported as Span LOs count. So the total ADC acquisition time for a given span, aka Sweep Acq. Time, is the product of Acquisition time for 1 LO x Span LO count (unless Multiple Recording mode is running, then the Multiple Recording multiplication factor is to be considered).

The entire sweep time is a significantly larger number than the Sweep Acq. Time. Each time the LO is moved, there is a settling time required for LO stabilization. Then each time some raw ADC data is acquired, there is some time to move the data across the buses (the data amount is multiplied by the number of ADCs at work, when several RF receivers are acquired). All the further processing (windowing, DFT, IF calibration, Image Rejection, User calibration) is CPU time consuming, the lowest the RBW the more time it takes to process the DFT samples (there are more DFT samples).

The Image Rejection mode MIN instead of Normal (when not running coherent mode) is a popular way to speed up the sweep time, as roughly half of the LOs count is required, at the cost of higher likelihood of false spectrum spurious (but real signal spurious are still always detected).

The video averaging is digital, it runs several times the ADC acquisitions and windowing and DFT and then averages. The number of times this extra processing is done for video averaging is indicated at the Video averaging count at the SA main page.

When available, the vector averaging is done at the FPGA side, it multiplies by the averaging factor the ADC acquisition time, and it doubles the data amount across the data buses (32 bits instead of 16 bits ADC data representation). The following parts of the processing are not impacted, the quantity of data to process at host CPU side is not increased. Thus the vector averaging is a very efficient way to get lower noise floor with minimum additional CPU time.
The display processing is a very significant part of the sweep time. The number of display points can be set (defaults to 1001), then the code often has to do a data reduction to go from millions of DFT points to 1001 display points. This is the so-called detector processing. This process is CPU intensive, especially the Peak detector that recomputes an X-axis frequency grid each sweep to align each x-axis point to the local interpolated peak. FastPeak is less frequency accurate for the peak points positions but very significantly faster. If the span is narrow, bypassing the detector can speed up the sweep. Turning off the display is another option, it bypasses most detection and display algorithms, thus speeds up the sweep in remote programming modes.

The status bar of the channel shows the last measured SA sweep time, and if some settings are changed, the first sweep after a change shows an estimate with a ~ preceding the timing.

ADC & LO Dialog tab help

**ADC Sampling**

**ADC Sample Frequency** - Select between 100 MHz and 25 MHz.

**Auto** - Check to automatically set the ADC Sampling Frequency.

**Enable FIR for 25 MHz** - Enables the FIR filter for 25 MHz decimation: reduces the noise floor.

**Dithering** - Check to allow ADC dithering to average out the characteristic "stair steps" produced
during the ADC conversion process.

**Overrange warning percent** - Sets the percentage of the ADC input full scale. SA sweeps require thousands (or millions) of ADC samples processed by the FFT. The maximum ADC sample value is kept for the whole sweep, as it is an image of the peak voltage in the IF chain of the instrument. Instead of calibrating this value to Volts, a percentage value of the ADC input full scale is used. If the value is too high, reduce the IF gain or add RF attenuation to maintain the linearity of the instrument. If the value is too low, the signal amplitude is too low and under-utilizing the ADC range. Increasing the IF gain may increase the measurement quality (reducing the noise floor).

**Show ADC Ranges...** - Displays the ADC ranges of the current receivers from the last sweep if the Trigger mode is currently on Hold.

![ADC Ranges](image)

**ADC Raw data**

**Force ADC record size** - Sets the ADC record size which is dependent on the Resolution Bandwidth and ADC Sampling Frequency:

\[
ADC \text{ Record Size} = \frac{1}{ResBW} \times ADC \text{ Sampling Frequency} \times Window \text{ Expansion Factor}
\]

**Check box** - Check to enable the ADC record size to be specified manually. Doing so sets the resolution bandwidth. The size range is 64 Samples to 32 or 64 MegaSamples depending on the selected receivers. The DFT size will be recomputed accordingly to the DFT Type setting. When not checked, the value displayed is the current ADC record size. This feature is not compatible with Coherent Multitone mode.

**Stacking** - Stack ADC samples by the specified number (=1) and store result in memory. For example, if an ADC record size of 1,000 samples is acquired and Stacking is set to 1, then 1,000 samples will be added to 1,000 samples and the result (1,000 samples) will be stored in memory. In other words, we acquire 2,000 samples form ADCs and send 1,000 stacked samples to the next processing stage. Stacking helps to reduce noise and increase dynamic range. However, this feature should only be used when the stimulus frequencies are known and coherent with the current ADC record size. A value
of 0 means no stacking.

**Check box** - Check to enable the ADC sample stacking to be specified manually.

**Note:** Stacking and Video Bandwidth averaging cannot be set together; Video Bandwidth has precedence. The ADC Record Size x (Stacking + 1) must be =64 Mega Samples.

**Note:** Stacking is a great averaging method when Coherent Multitone mode is enabled. We recommend increasing the stacking in Coherent Multitone mode instead of reducing the RBW in order to reduce the noise floor.

**Multiple Recording** - Check to allow the ADC Record Size to be divided and acquired in smaller "chunks" and also specify a wait period between these acquisitions.

- **Chunk Size** - Sets the size to acquire the ADC record in smaller "chunks". For example, if the ADC Record Size is 2048 and the **Chunk Size** is set to 256, then the ADC record is acquired in 8 chunks (1 = Chunk Size = ADC Record Size).

- **Chunk Period** - Set the period to wait between ADC record chunks.

**Note:** This feature is compatible with Coherent Multitone mode.

**LO**

**Randomized LO** - Check to allow dithering of the LO values used when taking a sweep. Allowing randomized LO makes it less likely that erroneous signals will appear in the final measurement.

**Enable baseband X-axis mode (LO independent sweep)** - Enables baseband sweep independent of the LO sweep to allow signals down to 1 Hz to be analyzed. This function is called baseband because it operates without LO conversion and also does not use the mixer path in the IF. The frequency range that can be measured is 1 Hz to 38 MHz due to the IF filter. Therefore, spectrum analysis can be done within this range.

**The following is a procedure for using this function:**

1. Check the **Enable baseband X-axis mode (LO independent sweep)** check box.

2. Connect the signal through one of the IF Path Inputs on the rear panel. Learn more .

3. Go to the **SA** tab and change the **Stop** frequency to 38 MHz. Notice the **Start** frequency changes to 10 MHz. Change the **Start** frequency if necessary.
4. Go to the IF tab, click on the IF Config... button, then under IF Path for the IF inputs you want to consider, select External.

![IF Path Configuration](image)

**Note:** The SA baseband mode only allows you to run one R receiver. Any R receiver selection (R1 to R4) will get the signal from the R IF input.

5. In the IF tab under IF Bandwidth, deselect ADC Filter Auto and select Wide 38MHz. This allows you to change the Wide frequency range if necessary. If the SA current span is larger than the IF bandwidth, -200 dBm will be displayed outside of the IF filter area.

![IF Bandwidth Configuration](image)

**Force LO to Frequency** - Sets the LO to a specified frequency. This check box can only be set if Image Reject is set to None, LO Low or None, LO High or Enable baseband X-axis mode (LO independent sweep) is checked.

**Check box** - Check to enable the LO frequency to be specified manually.

This function allows the LO source to be used mostly like another source that can be set up relative to a source port. For example, if Port 1 in the Source tab is set to a frequency of 1 GHz and the **Force LO to frequency** is set up as shown below, then the LO will track 1 MHz after the Port 1 source frequency.
Data Dialog tab help

Data Format -

- **Float LogMag (dB)** - Sets the data format to log magnitude in dBm.
- **Float LinMag** - Sets the data format to linear magnitude in volts.
- **Integers** - Sets the data format to Packed Integers (each value is a short 16 bit integer, the equation to compute the dBm value is: dBm = Xshort/200.0 - 36.165.

**Export receivers** - Select the data to export from a specific receiver or all receivers.

**Don't save data below threshold** - Set data level threshold mode and threshold level in dBm. For text file output with verbose mode, only the frequencies with power greater than this threshold setting will be written to the file.

**DFT bins count** - Displays the current DFT bin count, the number of DFT points processed across the total RF span. When the Detector is bypassed, this is the number of points that
are sent to the display.

**Receivers count** - Displays how many receivers are currently being exported. The number here can be less than the number of receivers specified in Export Receivers, if some of them are not selected in the channel.

**Export to binary file** - Set data to be exported to a binary file. Data is not exported until the next new sweep occurs.

**Export to text file** - Exports data only. Data is not exported until the next new sweep occurs.

**Verbose mode** - Exports frequency and data. Data is not exported until the next new sweep occurs.

**Erase files each new sweep** - Selecting this option will erase the data after each sweep. If this option is not checked, the data from each sweep will continue to be appended to the output data file which can create a very large file size (and fill the disk, with many unwanted consequences).

**File name prefix** - The receiver selected in Export receivers will be appended to the prefix name specified in this field with either "*.txt" if a text file is exported or "*.bin" if a binary file is exported. For example, if C:\Temp\SA_DATA_OUT is entered into the File name prefix field and the "B" receiver data is exported to a text file, the data will be exported to a file called SA_DATA_OUT_B.txt.

**Record size (bytes)** - This is the byte size of binary data output.

**Export markers with data files** - Adds marker data and data to the text file (*.txt) output.

**Export all markers to a single file** - Adds all marker data to a single text file (*.txt) output.

**Export to FIFO buffer** - Exports data to the FIFO (First-IN, First-OUT) data buffer. FIFO is a circular buffer that allows very fast Read-Write access.

**Export to shared memory** - Exports data to shared memory (Microsoft Windows feature) which is the fastest way to transfer data between applications. The application that is retrieving data has to register itself to Microsoft Windows with the same share name.

**Share name** - Assigns a specified name to the shared data.
In the SA Setup Source Tab (above):

> When (Sweep) Type = **CW**, set the CW Frequency.

![Frequency Settings](frequency_cw.png)

> When (Sweep) Type = **Linear**, the following dialog appears:

![Frequency Settings](frequency_linear.png)

**Settings**

Sets the source frequency range. Use either of the following pairs of settings to set the frequency range.

- **Start /Stop** - Specifies the beginning and end frequency of the swept range.
- **Center /Span** - Specifies the value at the center and frequency range.

**Source Number of Steps** - Sets the number of steps the source will make across the specified source frequency range.

**SA Sweeps / Source Step** - Sets the number of SA (receiver) sweeps for each Source Step. This setting is common to all sources.
In the SA Setup Source Tab (above):

> When (Sweep) Type = CW, or LinFreq, the following dialog appears:

![Power Settings dialog](Image)

> When (Sweep) Type = Power or LinF+Pwr, the following dialog appears:

![Power Settings dialog](Image)

**Settings**

Sets the source power range. Use either of the following pairs of settings to set the power range.

**Start /Stop** - Specifies the beginning and end power of the swept range.

**Center /Span** - Specifies the value at the center and power range.

**Source Number of Steps** - Sets the number of steps the source will make across the specified source power range.

**SA Sweeps / Source Step** - Sets the number of SA (receiver) sweeps for each Source Step. This setting is common to all sources.
In the SA Setup Source Tab Phase column (above):

> When (Sweep) Type = \textbf{CW} or \textbf{LinFreq}, \textbf{Power}, or \textbf{LinFreq+Pwr}, the following dialog appears:

![Phase Settings dialog](image)

> When (Sweep) Type = \textbf{Phase}, \textbf{Freq+Pha}, \textbf{Pow+Pha}, or \textbf{Fr+Pw+Ph} the following dialog appears:

![Phase Settings dialog](image)

**Settings**

Sets the source phase range. Use either of the following pairs of settings to set the phase range.

- **Start /Stop** - Specifies the beginning and end phase of the swept range.

- **Center /Span** - Specifies the value at the center and phase range.

**Source Number of Steps** - Sets the number of steps the source will make across the specified source phase range.

**SA Sweeps / Source Step** - Sets the number of SA (receiver) sweeps for each Source Step. This
Setting is common to all sources.

**Measurement Parameters**

**How to select and configure Measurement Parameters**

**Using Hardkey / SoftTab / Softkey**

1. Select a trace by pressing `Trace > Trace N > Trace N`.
2. Press `Trace > Trace Setup > Measure...`.
3. Select a parameter.

**Using a mouse**

1. Right-click on a trace.
2. Select a parameter.

**Measure Dialog**

Select one of the test port receivers to make a measurement. Test ports are identified in both traditional VNA notation and Receiver Notation. Learn more.

Or select an ImageReject measurement, if the Display Image Reject Traces checkbox has been set.

**New Trace** - Add a new trace.

**Channel N** - Select a channel number for the new SA trace.
**Window N** - Select to create the new trace in an existing window or new window.

**Select All** - Select all measurement parameters.

**Note:** Configuring an external DC meter for a SA channel is supported. DC is read at the end of a sweep. Only one point is read and the entire trace is filled with this point reading regardless of the number of channel points.

---

**Marker -> SA**

The following marker-related features are unique to SA.

**Marker -> SA**

This feature is supported in Standard, SMC or Swept IMD measurement classes (channels) ONLY. In this section, these are called NA channels.

On a standard channel with a marker residing on a trace in an NA channel, **Marker -> SA** creates a new SA channel in full frequency span and provides access to the SA Analysis Markers.

Refer to the following for swept IMD and SMC:

Swept IMD: span = 10 * delta frequency

SMC: SA channel uses receiver frequency range

A marker is created on the trace at the same frequency as the NA channel marker. This is a quick way to see the frequency spectrum of the NA channel at a specific frequency.

- The same source that is used for the trace in the NA channel is turned ON in the SA channel in CW mode at the marker frequency.

- The same receiver that is used for the NA channel is used for the SA channel.

- For each new NA channel, a new SA channel is created. Subsequent markers in the same NA channel use the same SA channel.

- In general, **Marker -> SA** creates a new measurement on the SA channel only if the measurement does not already exist. For example, if a marker is used on an S11 measurement in a standard channel, **Marker -> SA** creates a measurement using test receiver "A" with port 1 as the source. If **Marker -> SA** on an S12 measurement is then performed, the same test receiver "A" is used except that port 2 becomes the source. In this case, a new SA trace will not be created.
How to use Marker \text{ -> SA}

With a marker residing on a trace in a standard channel...

- With a mouse: Right-click on a marker, then select Functions, then Marker \text{ -> SA}.
- With a keyboard: With the relevant marker active (selected), Alt+M, F, A.
- Without mouse or keyboard: With the relevant marker active (selected), Press Marker, Marker \text{ -> Functions}, then Marker \text{ -> SA}.

\textbf{Band Markers}

Once an SA channel has been created using Marker \text{ -> SA}, the Band Markers are accessed by selecting the SA Analysis softtab. The following marker types provide a readout of the total power, noise, or density within a selectable frequency span. The span is marked by vertical posts that appear on either side of the marker.

- Band Power - These markers provide a readout of the total power within a specified frequency span defined by Band Span.
  
The Average detector type makes the display more consistent with Band Power markers. With this detector type the marker readouts and the estimated power values or delta from the display have a good match. Many legacy spectrum analyzers need to set the detector type to average to do band power measurements. PNA-SA does not need to select the average detector to compute the right band power measurements, it's only useful to check the values between marker readouts and display estimates.

- Band Density - Select Off, Noise (dBm/Hz), Power (dBm/Hz), Tone (dBm/Tone), NPR, or ACPR.

Refer to SA Analysis Markers for a full description of the marker types and their settings.

\textbf{Band Power and Band Density Noise Markers}

\textbf{Note:} If a Band Power or Band Density Noise marker is selected, Discrete mode is turned OFF to allow precise measurements over the desired frequency range.

The span is marked by vertical dotted lines that appear on either side of the marker. The marker's y-axis value is set to the measured power value.
If a Band Power or Band Density Noise marker is in Delta mode, the difference between the Band Power or Band Noise marker and the reference marker is displayed with a leading delta symbol.

**Band Density Power Markers**

The ? 1 marker displays the notch frequency relative to the center frequency. In this example the notch is in the center so the frequency is 0 Hz. Also displayed is the notch span (100 MHz).
The Tones is the difference between the average tone power a the Reference (> R ) marker and the average tone power at the bottom of the notch.

The > R marker displays the center frequency (16 GHz) and the signal span (1.5 GHz).

The Band Power displays the total power within the signal span.

The Tones (1.40 GHz) displays the average tone power across the 1.5 GHz signal span minus the average tone power across the notch (1.5 GHz - 100 MHz = 1.4 GHz)

The total modulation span defined by Band Span is marked by the outer vertical dotted lines.

Each notch is also marked with vertical dotted lines defined by Density BW.
How to select Band Markers

1. Press Marker > SA Analysis.

2. Another method of selecting band markers is to right-click on a marker on the display then select Search then Search... from the menu. The following dialog appears:

![Marker Search dialog](image)

3. For information on the settings for different SA search types, refer to SA Analysis Markers.

If a Band Power or Band Noise measurement cannot be made, the marker readout will display -999.
dBm (for Band Power), or -999 dBm/Hz (for Band Noise). There are two reasons why this may happen:

1. *The band span (from marker frequency – span/2 to marker frequency + span/2) is outside the frequency range of the channel.*

2. *The Band Power or Noise marker was created while the channel was in Hold mode. At least one sweep must be taken after creating such a marker. The marker can be moved taking a sweep while in Hold mode. However, the marker readout will not change. To update the marker readout to the new marker location, a re-sweep is required.*

**Occupied BW Ratio**

The Occupied BW Ratio is the frequency range that contains a defined percentage of the overall band power as specified by OBW Percent. The marker readout provides the occupied band center frequency, percentage of the band span to measure, and the occupied band power. See also Occupied BW search min for setting the minimum frequency to start a search.

The span is marked by vertical dotted lines that appear on either side of the marker indicating the percentage of span. The marker's y-axis value is set to the measured power value.
How to select Occupied BW Ratio

1. Select one of three ways to enable Occupied BW Ratio:
   
   a. Move the cursor on a marker, right-click on the marker, select Search, then Occupied BW.
   
   b. Press Marker, then SA Analysis, then Occupied BW ON.
   
   c. Select Response, then Search...
      The following dialog appears

   ![Marker Search Dialog]

2. If the Marker Search dialog is used, perform the following steps:
   
   a. Select an existing marker.
b. For Search Type, select Occupied BW Ratio.

c. For Percent, enter a percentage of the band span to search.

d. For Search Domain, either select Full Span (default) or define a User Span by selecting User N then specifying the Start and Stop frequencies.

e. Click OK.

---

**Calibrating an SA Channel**

A calibration can be performed on the SA Channel using the Cal All Wizard when corrected results are required to improve amplitude accuracy.

**Note:** Calibration is performed over the currently specified spectrum analyzer frequency range only.

Another method of calibration is to import an existing Cal Set. An imported Cal Set must contain the Receiver Response terms for the measurement port on the SA channel. In addition, if the imported Cal Set covers a narrower frequency range than the SA channel, the error terms in the imported Cal Set are extrapolated.

The Cal Plane Manager can be used to characterize adapters, cables, and fixtures used to connect a DUT to the VNA to remove their effects from the measurement. See the detailed procedure.

---

**Gated SA**

Gated spectrum analyzer measurements are triggered measurements that capture data for the duration of the active level of the trigger. Thus, only level external triggers can be used (High level, Low level) for gated measurements. Edge triggers can be used to start SA measurements, but will not gate them. It is not recommended to use level triggers to start measurements: if the active level is shorter than the required acquisition time (that depends on the RBW and other settings), then the measurement will abort.

A given SA sweep needs a given number of LOs (this depends mainly on the span and on the Image Reject setting). This number can be retrieved at the SA Processing dialog. Each LO needs one ADC acquisition and the duration of one ADC acquisition can be retrieved at the SA Processing dialog. The time for each LO acquisition is based on the ADC Record Size times the ADC Sampling Frequency (defaults to 10 nsec). For gated SA, it is meaningful to gate each individual ADC acquisition. This can be done with the Trigger Setup dialog, with the external trigger configured per channel (Trigger Scope) in point mode (channel trigger state mode), and Meas Trigger set to Level.
For example, if the ADC Record Size is 663, the time required for a full DFT acquisition would be 663 x 10 nsec = 6.63 usec. As long as the width of the measurement trigger is greater than 6.63 usec, measurement data will be acquired. If the measurement trigger width is set to less than 6.63 usec, then no measurement data will be acquired. If the width of the measurement trigger is much larger, for example 20 usec, then up to 3 ADC acquisitions with 663 samples can occur during the active status of the trigger.

**Note:** Internal Pulse0 pulse generator is not suitable for gated SA because the pulse width cannot be set. Instead, use Pulse3 as shown in the Gated Measurement example (pulse 1 to pulse 4 would work too, but without the direct Trigger source to Pulse3 internal connection).

Refer to Gated Measurement for an example of how to set up a gated spectrum analyzer measurement.

**SA Warning Messages**

Warning messages appear when the measurement cannot be performed with the current settings. Messages are displayed in blue for three seconds and the channel is placed in hold (not sweeping).

SA Warning: Image Reject Max and Better are not allowed if RBW > 1MHz and Narrow IF Filter.

SA Warning: Image Reject Max is not allowed if RBW > 1MHz.

SA Warning: Image Reject Better is not allowed if RBW > 2MHz.

SA Warning: Image Reject Max and Better are not allowed below 20 MHz if RBW > 1MHz and Wide IF Filter.

SA Warning: Cannot run Image Reject None LO High at high end of RF frequencies.

SA Warning: Cannot run Image Reject None LO Low at low end of RF frequencies.

SA Warning: Cannot force Narrow IF Filter if RBW > 1MHz.
Noise Power Ratio (NPR) Settings

NPR measures the nonlinear behavior of an RF microwave amplifier under a modulated signal stimulus.

In this topic:

- Requirements
- Create a Spectrum Analysis Channel
- Accessing NPR Settings
- Modulation settings dialog
- Create Modulation dialog (separate topic)
- Modulation Cal - Setup dialog (separate topic)

See Noise Power Ratio (NPR) Measurement Example

Requirements

- Spectrum Analyzer Option S9x090xA/B
- 2- or 4-Port PNA with ability to connect an external modulated source
- Supported external sources:
  - E8267D PSG Vector Signal Generator
  - M8190A with E8267D PSG Vector Signal Generator
  - M9383A/B, M9384B (wideband vector, 44 GHz, with enhanced phase noise)

Note: When setting up an M9383A, M9383B, or M9384B source in the External Device Configuration dialog, select **MXG_Vector** as the driver (they are code compatible).

- N5182B MXG RF Vector Signal Generator
- N5192A and N5194A UXG Vector Adapter
Create a Spectrum Analysis Channel

1. On the VNA front panel, press Meas > S-Param > Meas Class....

2. Select Spectrum Analysis, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.

3. A Spectrum Analysis measurement is displayed.

Accessing NPR Settings

Using Hardkey/SoftTab/Softkey

1. Press Freq > Source IQ Mod. > MXG.

Using a mouse

1. Click Stimulus
2. Select SA Setup...
3. Select the Source tab.
4. Click in the IQMod column then select Edit.

Modulation settings dialog help
**Modulation source** - Displays the name of the modulation source.

**Enable Modulation** - Check to enable modulation.

**Create/Edit Mod File...** - See Create Modulation dialog description.

**Show File Properties** - Displays the properties found in the modulation file. This is the active Modulation Filename selected in the Modulation settings dialog. This information cannot be edited.
**Modulation Filename** - Selects the modulation file.

**Autoset Frequencies and Coherence for current modulation.**

**Autoset NPR Markers** Enables and disables NPR markers.

**Autoset ACPR Markers** Enables and disables ACPR markers.

**NPR Band Guard** - Guard band on each side of the notch in an NPR measurement.

**ACPR Band Guard** - Guard band between the end of the modulation signal and where ACPR is measured.

**Immediate Autoset** button - Click to adjust frequencies and markers if modulation settings are changed.

**Enable Modulation Correction** - Automatically checked if user exits the calibration wizard with **Exit & Save Cal**. This option is grayed out if a modulation calibration has not been performed.

**Source Amplification (= Power Offset) = 0.000 dB** - Displays the Power Offset to monitor the power budget between the source and DUT. The Power Offset setting provides a method of compensating port power for added attenuation or amplification in the source path. [Learn more.](#)
Calibrate Modulation... - See Modulation Cal - Setup dialog description.
The Intermodulation Distortion (IMD) App is offered for both Amplifiers and Converters, and also can be viewed in both Swept IMD and IM Spectrum channels.

- **Swept IMD** channels are used to measure over 150 different IMD parameters. These parameters are built from various selections such as: IMD products, tone power levels, intercept points, at the input and/or output of a DUT. In addition, each parameter can be swept using several different methods.

- **IM Spectrum** measurements provide a traditional spectrum analyzer view of the main tones and distortion products.

Learn all about the IMD App (Opt S93087A/B) in the following topics:

**Concepts**

- Swept IMD and IM Spectrum Concepts

**How to Use ALL IMD Apps**

Swept IMD (Intermodulation Distortion) Concepts

When a device or system is subjected to multiple input frequencies, the non-linearity of the DUT can generate undesired outputs at other frequencies. Typically, two input tones of equal power separated in frequency by a specified amount are used to stimulate the device while observing the resulting frequency spectra at the output. A variety of measurements can then be utilized to determine the intermodulation distortion characteristics of the device.

The frequencies of the resulting distortion products are predictable. While many mixing products can be generated, the high and low signals of the "odd order" products (3rd, 5th, and so forth) are close enough to the original two signals to potentially interfere with adjacent communication channels. With the exception of the 2nd order product, the higher "even order" products are usually far enough away to be of no interest.

The following image and table shows two equal-power main-tones and the nearby odd-order distortion products, as well as the 2nd order product (not shown in the image). Notice that the frequency separation between adjacent odd-order products is the same as the separation of the main tones (Delta F) frequency. For most devices, these distortion products become worse as the device is pushed further into compression.
Two main tones (f1 and f2) with odd order intermodulation products.

The following table shows the calculations and example frequencies (Blue text) of the intermodulation products that are closest to the two main tones.

<table>

Learn about Swept IMDx for Converters Concepts

Swept IMD Parameters

The following basic parameters, offered for both Amps and Converters, are expanded to over 150 by selecting specific product tones (2,3,5,7,9), the Low-side, High-side, or Average of these tones, measured at the Input or Output of the DUT.
• Tone Power
• Tone Gain
• Intermodulation Distortion
• Intercept Point Parameters
• Composite Triple Beat (CTB)
• Composite Second-order Beat (CSO)
• Cross-Modulation Distortion

Learn how to select these IMD parameters.

**Tone Power Parameters**

Tone Power parameters measure the **absolute** power level of the main tones, odd-order product tones up to the 9th order, and the 2nd order product tones. These tone powers can be measured at the input and output of the DUT. Because the tones come in pairs, the **Low tone**, **High tone**, and the **Average** of the two can be measured and displayed.

The Average Tone Power is calculated as follows:

$$\text{Avg} = \frac{(\text{High tone (dBm)} + \text{Low tone (dBm)})}{2}$$

When measuring the 2nd order products, only the Low tone and High tones are allowed. When the main tones are separated by less than 10 MHz, the Low tone (f2-f1) is below the frequency range of the VNA.

**Tone Gain**

Tone Gain (in dB) calculates the main tone Output Tone power / Input Tone power. Because the tones come in pairs, Tone Gain can be calculated for the **Low tone**, **High tone**, and the **Average** of the two as indicated in the Average Tone Power calculation.

For IMDx for Converters, the Input and the Output tones are typically at different frequencies.

**Intermodulation Distortion Parameters**

IMD parameters measure the **difference** in power level between the specified product tone and the main tones. These IMD parameters are calculated from the Tone Power measurements. IMD parameters can measure the odd-order product tones up to the 9th order, and the 2nd product tones, at the DUT Input or Output. For each specified product, the difference between the **Low** product and main tone, difference between the **High** product and main tone, and difference between the **Averages** of the product and main tone can be measured and displayed.
Swept IMD supports IMD parameters which are calculated as follows:

<table>
<thead>
<tr>
<th>IMxLo</th>
<th>PwrxLo-PwrMainLo</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMxHi</td>
<td>PwrxHi-PwrMainHi</td>
</tr>
<tr>
<td>IMx</td>
<td>Pwrx-PwrMain</td>
</tr>
<tr>
<td>IMxLoIn</td>
<td>PwrxLoIn-PwrMainLoIn</td>
</tr>
<tr>
<td>IMxHiIn</td>
<td>PwrxHiIn-PwrMainHiIn</td>
</tr>
<tr>
<td>IMxIn</td>
<td>PwrxIn-PwrMainIn</td>
</tr>
</tbody>
</table>

where:

- \( \times \) = the IM product of interest (2, 3, 5, 7, 9)
- \( \text{Avg} \) is implied if \( \text{Hi} \) or \( \text{Lo} \) is not stated
- \( \text{Output} \) is implied when \( \text{In} \) is not stated

Learn how to select IMD parameters.

**Intercept Point Parameters**

As the main tone output power increases (black arrow), output power in the specified product tone increases at a predictable, and steeper, rate (green arrow). At some point, the power in the product tone will be equal to the power in the main tone. The power level at which this occurs is known as the intercept point. Measuring this point directly is typically not possible. Therefore, it is calculated by measuring the main tone power and the specified product tone power.
The Swept IMD App can display either the DUT Input power or DUT Output power that is required to achieve the theoretical intercept point. This is called either Input Referred (IIP) or Output Referred (OIP).

This measurement can be made for the 2nd, 3rd, 5th, 7th, and 9th order intercept points. In addition, the measurements can be made for either the Low tone, the High tone, or the Average of the two. However, for the 2nd order intercept point, only Low and High tone parameters are supported; not Average.

Swept IMD supports Intercept Point parameters which are calculated as follows:

\[
\begin{align*}
OIPxHi &= PwrMain - IMxHi/(x-1) \\
OIPxHiIn &= PwrMain - IMxHiIn/(x-1) \\
OIPxLo &= PwrMain - IMxLo/(x-1) \\
OIPxLoIn &= PwrMain - IMxLoIn/(x-1) \\
OIPx &= PwrMain - IMx/(x-1) \\
OIPxIn &= PwrMain - IMxIn/(x-1) \\
IIPxHi &= PwrMainIn - IMxHi/(x-1) \\
IIPxHiIn &= PwrMainIn - IMxHiIn/(x-1) \\
IIPxLo &= PwrMainIn - IMxLo/(x-1) \\
IIPxLoIn &= PwrMainIn - IMxLoIn/(x-1) \\
IIPx &= PwrMainIn - IMx/(x-1) \\
IIPxIn &= PwrMainIn - IMxIn/(x-1)
\end{align*}
\]

where:

- \( x \) = the IM product of interest (2, 3, 5, 7, 9)
- \( PwrMain \) = average power of the main tones at the DUT Input or Output
- \( IMx \) = product tone power - main tone power (from above IMD parameter)
- \( Avg \) is implied if \( Hi \) or \( Lo \) is not stated
- \( Output \) is implied if \( In \) is not stated

Learn how to select IMD parameters.

**Composite Triple Beat (CTB)**
From the NCTA Standard, composite triple beat is defined as the modulation beat of the target channel signal caused by triple beat resulting from the nonlinear characteristic of the DUT. Composite triple beat is expressed as the ratio of the target channel signal level to the maximum mean level of beat components dispersed around the carrier of that target channel.

Swept IMD supports two parameters of this type:

- CTB is based upon an approximation for the number of beats in mid-band
- CTBE is based upon an approximation for the number of beats at the band edge.

The equations for these two parameters are as follows:

Mid-Band CTB (dB) = \(-2(P_i - P_s) + 6 + 10 \log(3N^2/8) + \text{CTB Offset}\)

Band Edge CTBE (dB) = \(-2(P_i - P_s) + 6 + 10 \log(N^2/4) + \text{CTB Offset}\)

Where:

- \(P_i\) = Output power level at the third order intercept point (dBm): OIP3 (Lo | Hi)
- \(P_s\) = One of the following values based upon the Composite Normalization Mode:
  - For PDBM or PDBMV mode, \(P_s = \text{CompositeNormalizedCTBPower}\)
  - For Number of Carriers mode, \(P_s = \text{PwrMain (AVG)} - 10 \log(N/2)\)
  - For None mode, \(P_s = \text{PwrMain (AVG)}\)
- CTB Offset = Offset value for CTB calculation
- \(N\) = Total number of carriers.

**Note:** CTB Offset and \(N\) values can ONLY be set using SCPI or COM commands.

Learn how to select IMD parameters.

**Composite Second-Order (CSO)**

From the NCTA Standard, composite second order is defined as the modulation beat of the target channel signal caused by second order beat resulting from the nonlinear characteristic of the DUT. Composite second order beat is expressed as the ratio of the target channel signal level to the maximum mean level of beat components dispersed around 0.75 MHz and 1.25 MHz above and below the carrier of that channel.

Swept IMD supports a CSO parameter which is calculated as follows:
CSO(dB) = (Pi - Ps) + 10Log(N) + CSO Offset

Where:

- **Pi** = Output power level at 2nd order intercept point: OIP2 (Lo | Hi)
- **Ps** = One of the following values based upon the Composite Normalization Mode:
  - For **PdBm** or **PdBmV** mode, **Ps** = CompositeNormalizedCSOPower
  - For **Number of Carriers** mode, **Ps** = PwrMain (AVG) – 10Log(N/2)
  - For **None** mode, **Ps** = PwrMain (AVG)
- **CSO Offset** = Offset value for CSO calculation
- **N** = Number of distortion products.

**Note:** **CSO Offset** and **N** values can ONLY be set using SCPI or COM commands.

Learn how to select IMD parameters.

**Cross-Modulation Distortion**

From the NCTA Standard, cross modulation is defined as the distortion that causes modulated carrier components of undesired channels to amplitude-modulate the target channel carrier due to the nonlinear characteristic of the unit under test. Cross modulation distortion is expressed as the ratio of the target channel carrier level to the level of modulated components of the carrier of the target channel resulting from modulated signals of undesired channels.

Swept IMD supports an XMOD parameter which is calculated as follows:

\[ XMOD = -2(Pi - Ps) + 6dB + 20Log(N) \]

Where:

- **Pi** = Output power level at third order intercept point: OIP3 (Lo | Hi)
- **Ps** = Power level of each carrier: PwrMain (AVG)
- **N** = Total number of carriers.

Make Cross Modulation settings using SCPI or COM commands.

**How the IMD Application Works**
The following diagram illustrates how the VNA is configured to generate the two main tones. This shows a PNA-X with dual sources and the internal combiner. A 2-port or 4-port N522xA model can also be used. Learn how to Configure External Source and Combiner.

2-port PNA-X generates the f1 and f2 main tones.

Depending on the specified parameters and sweep type, the sources and receivers are tuned to the appropriate frequencies in order to measure all of the required main and product tone powers. For example, an IM3 parameter requires the measurement of both main tones, and the 3rd order High and Low tone powers.

The Narrowband IF path is used for IMD measurements to help reduce spurious responses. Because the narrowband filter has a bandwidth of about 28 kHz, using an IFBW greater than 30 kHz does nothing to improve measurement accuracy. Learn how to set IFBW for IMD.

Limiting Stimulus Settings and Out of Range Product Tones

Because the main tones are generated by the VNA internal sources and external sources, the frequencies of the main tones must always be within the frequency range of the VNA or external source. Sweep parameter values are adjusted when necessary to ensure that f1 and f2 frequencies are within these limits.

However, the VNA DOES allow you to make settings that cause the selected IM products to fall outside the frequency range of the VNA. For example, with the main tones at 10 MHz and 15 MHz, the VNA will allow you to select the parameter IM3Lo (3rd low side product tone). However, the frequency of this product will be at 2f1-f2 or 5 MHz, which is below the frequency range of the VNA. In these cases, the trace data is set to zero, which converts to -200 dB in Log Mag format.
**Limited Number of Acquisitions**

The total number of acquisitions per sweep can not exceed 32,001 points. The number of acquisitions is determined by multiplying the number of trace points, by the number of tones frequencies, then by 2 (for both Input and Output frequencies). The VNA will automatically reduce the number of trace points to ensure the total number of acquisition points does not exceed 32,001.

**How an IM Spectrum Channel Works**

Before reading this topic, you should become familiar with [IMD Concepts](#).

The IM Spectrum channel provides a traditional spectrum analyzer view of the intermodulation distortion behavior of a device. Unlike the Swept IMD channel, the main tones (F1 and F2) are fixed while the receiver is swept over a frequency range of interest in order to generate a display as shown below.

![IM Spectrum trace (bottom) with Swept IMD traces (top)](image)

A typical spectrum analyzer does NOT have a signal source. This one does. The signal source, or stimulus, settings for the F1 and F2 main tones can be set in either the IM Spectrum channel or the Swept IMD channel. These settings include the frequencies and power levels of the main tones.
The settings for the IM Spectrum receiver can be set ONLY in the IM Spectrum channel. These settings include how many tone products to view - which determines the center and frequency span - and the Resolution Bandwidth.

You can choose from several Resolution Bandwidths which also determines the number of data points used in the channel. The higher the Res BW, the fewer the number of data points. The formula for determining the number of points is:

\[ N = \frac{\text{Span}}{\text{ResBW}} \times 3 \]

The IM Spectrum channel performs multiple measurements for each data point in order to reject unwanted images which are generated by the VNA internally. This provides a high degree of confidence that signals captured in a trace are real and are not spurious responses generated in the measurement process.

**IM Spectrum Parameters**

You can select from three different IM Spectrum parameters.

1. The tones OUT of the DUT (default parameter).
2. The tones IN to the DUT (to be sure that the input signals are pure). **NOT supported** in IMx Spectrum
3. Reflected tones off the DUT input. **NOT supported** in IMx Spectrum

Learn how to select IM Spectrum parameters for Amplifiers or Converters.

Learn all about IM Spectrum for Amplifiers or Converters.

- How to specify IMD Parameters

IMD Calibration

Saving Swept IMD Power Data

Other IMD (Opt S93087A/B) Topics

Features and Limitations

See requirements.

Features

- Fast and easy setup for the measurement of a variety of distortion related parameters up to 9th order.
- Measurement at both input and output of a DUT.
- Supports a variety of sweep-modes for the main-tones: center-frequency linear and segment sweep, tone-separation sweep, power sweep, or CW sweep (fixed main-tone).
- Make very fast, accurate measurements using the VNA sources with high-power, high linearity, and low harmonics.
- Supports calibration and correction of Swept IMD parameters.
- Independently set IFBW for measuring main-tones versus product tones.

Limitations

- 2-port non-frequency converters ONLY. For frequency converters, use Swept IMDx.
DUT to VNA port mapping is limited. Port selections are made on the Power tab. Learn more.

When using Integrated Pulse application, the IF Filter setting for the relevant receiver must be changed to 'Wide'. Learn how. The default IF Filter setting in Swept IMD is 'Narrow' in order to avoid spurs and harmonics. The IF Attenuator setting (on the same dialog) may also require adjusting.

The following features are NOT available with Swept IMD:

- Number of points limited to 20,001
- Independent IFBW, Power Levels, or Sweep Time in a segment table is NOT supported.
- Analog Sweep (Stepped sweep mode only)
- Log frequency sweeps
- Unratioed receiver measurements (A, B, R)
- ECAl User Characterization
- Time Domain
- Balanced measurements
- Save Formatted Citifile data.
- Save SnP data.
- Port extensions
- Some Fixturing Features
- External Test Set Control (Option S93551A/B)
- Integrated Narrowband or Narrowband Pulse App
- External DC Sources (DC Meters ARE supported).
- See Frequency limitations in a Swept IMD channel.
- Option 205 or Option 425

Create a Swept IMD Measurement

1. Press Meas > S-Param > Meas Class....
2. Select Swept IMD, then either:
1. **OK** delete the existing measurement, or

2. **New Channel** to create the measurement in a new channel.

3. A Swept IMD measurement is displayed. To select additional parameters to display, click **Response**, then **Meas**, then select a parameter from the list.

### How to start the Swept IMD Setup dialog

**Using Hardkey/SoftTab/Softkey**

1. Press **Freq** > **Main** > **IMD Setup**.

**Using a mouse**

1. Click **Stimulus**
2. Select **IMD Setup**.

### Frequency tab - IMD Setup dialog box help

![Sweep Type and Sweep Settings](image)

Configures the Sweep Type and frequency range for SweptIMD and Swept IMDX measurements.

**Sweep Type and Sweep Settings**
Sweep fc (center frequency)

Maintaining a constant tone spacing (Fixed DeltaF) and tone power, fc is swept from Start fc to Stop fc. Center Frequency can also be specified as Center fc and Span fc.

At each fc, the receivers are tuned to all of the required frequencies to measure the power of the appropriate tones.

Swept DeltaF (tone spacing)

The specified fc (center frequency) and tone power is held constant. The tone spacing is increased from Start DeltaF to Stop DeltaF in the specified number of points.

Power Sweep

The main tone frequencies are specified as either f1 and f2, or as fc and DeltaF. These frequencies are held constant while the power of each main tone is varied from the Start-Power to Stop-Power in the specified number of power points. The power of each tone can be set (on the Power tab) individually or as a pair by checking Coupled Tone Power.

CW

The main tone frequencies and power levels are held constant. Measurements are taken for the specified Number of Points. The X-axis is number of points.

Segment Sweep fc (Swept IMD ONLY)

Same as Sweep fc except that the center frequencies are constructed using the standard segment table. Learn how.

LO Power Sweep (Swept IMDX ONLY)

The main tone frequencies and power levels are held constant. Measurements are taken for the specified number of points. The X-axis is LO Power.

Segment Sweep Notes: (Swept IMD ONLY)

- The segment table shown on the dialog is ‘READ-ONLY’.

- Learn how to Create and edit the Segment Sweep table.
- **Independent IFBW** and **Power** are NOT available.

- **X-axis point spacing** is available beginning with A.09.10.

**Number of Points** Enter the number of data points for each sweep. See Limited Number of Acquisitions.

**IFBW**

The **Narrowband IF path** is used for IMD measurements to help reduce spurious responses. Because the narrowband filter has a bandwidth of about 28 kHz, using an IFBW greater than 30 kHz does nothing to improve measurement accuracy.

**Main Tone and IM Tone IFBW** IF Bandwidth is specified separately for the main tones (f1 and f2) and for the intermodulation tones. This allows the higher-power main tones to be accurately measured at a higher - and faster - IFBW, while the lower-power product tones to be accurately measured a lower - and slower - IFBW.

**Note:** The IFBW is limited to 600 kHz when performing Swept IMD measurements even if the **Wide IF path** is selected.

**Reduce IF BW at Low Frequencies** - On the VNA, the trace noise becomes worse below 748 MHz. This is especially obvious between 10 MHz and 45 MHz. When this box is checked, the VNA uses a smaller IF Bandwidth than the selected value at frequencies below 748 MHz. Learn more about the selected values.

**Note:** For Main Tone IFBW settings of 1 kHz and below, and when the center frequency of the VNA is an exact multiple of 10 MHz, then the tone frequencies are shifted UP by (10 * IFBW) for the entire IFBW sweep. If those frequencies would exceed the maximum frequency of the analyzer, then the frequency is shifted DOWN by (10 * IFBW). This is done to avoid interference with 10 MHz reference signals.

---

**Power tab - IMD Setup** dialog box help
Configures RF power and Power Sweep settings for IMD measurements.

**Power ON (All channels)**  Check to turn RF Power ON or clear to turn power OFF for all channels.

**DUT Input Port**

**Input Port** Choose Port 1 or Port 3. When using Port 3, an external combiner is required. [Learn more.](#)

**Source Attenuator** Specifies the port 1 attenuator. This attenuator affects the range of available power into the DUT. [Learn more about Source Attenuation.](#)

**Receiver Attenuator** This attenuation setting protects the A receiver from damage.

**DUT Output Port**

**Output Port** Choose Port 2 or Port 4 (with limitations). [Learn more.](#)

**Source Attenuator** This setting is used to improve the load match at the DUT output. Select 0 dB for power levels up to 10 dBm, and increase by 10 dB for every 10 dBm more output power.

**Receiver Attenuator** Specifies the attenuator setting for port 2. When the power into the receiver test port is around +10 dBm, the VNA receiver may be in compression. However, with receiver attenuation, lower input power levels may become too noisy to make accurate power measurements. In this case, lower IFBW for the IM tones to reduce noise. [Learn more about Receiver Attenuation.](#)

**Tone Powers**

**Coupled Tone Power** Check to set the same power level for each main tone using the f1 Power setting. Clear to set different f1 and f2 power levels.

**ALC On** Check to use internal ALC hardware (default). Clear to use Open Loop hardware. Open Loop leveling should only be used when doing Wideband Pulse measurements.
Power Leveling

Because the gain of the DUT can be different for the f1 and f2 tone frequencies, you can set tone power at either the input of the DUT OR the output using the following methods. Receiver Leveling will cause slower sweeps.

Set Input Power (Default) The specified f1 and f2 power levels are set at the DUT input. Input power level accuracy is based ONLY on the source power cal that is performed during the IMD cal. The input and output tones may NOT be equal or flat.

Set Input Power, receiver leveling The specified f1 and f2 power levels are set at the DUT input using receiver leveling at the input reference receiver. This ensures the tone power levels are equal at the DUT input. However, the output tones may NOT be flat due to variations in the gain of the DUT at different frequencies.

Set Input Power, equal tones at output The specified f1 and f2 power levels are set at the DUT input and a measurement is made at the output. The inputs are adjusted once at each frequency to ensure the tone power levels are equal at the DUT output. However, the output tones may NOT be flat due to variations in the gain of the DUT at different frequencies.

Set Output Power, receiver leveling The specified f1 and f2 power levels are set at the DUT output. Receiver Leveling at the output receiver is used to accurately set the specified power level of each tone within the tolerance value that is set in the Receiver Leveling dialog. This setting results in the output tones being equal and flat across the frequency range.

Note: Enabling Safe Mode when using receiver leveling may be necessary to ensure stable results.

f1 / f2 Power

Fixed f1 Power Specify the power level for f1 at either the DUT input or output depending on the Power Leveling setting. Choose a value between -30 dBm and +30 dBm. When "Coupled Tone Power" is checked, power is set for both f1 and f2 tones.

Fixed f2 Power Available when Coupled Tone Power is NOT checked. Specify the power level for f2 at either the DUT input or output depending on the Power Leveling setting. Choose a value between -30 dBm and +30 dBm.

Start, Stop, and Step f1 and f2 Power Available when Power Sweep is selected on the Frequency tab. Sets the Start and Stop power levels for f1 and f2, either individually or together with Coupled Tone Power checked.

Path Configuration click to launch the RF Path Configuration dialog.

Highlighted Note: RF2 tone power offset to compensate for combiner loss.
This message appears when the f2 tone is being supplied by an external source. The tone power has been increased on the external source to compensate for loss through the internal combiner. For example, if the tone power at the DUT should be 0 dBm, the power out of the source will be about 15 dB higher.

To accommodate single-source VNA models, an external source can be used for the f2 tone. Learn how to configure an external source and combiner to make Swept IMD and IMDx measurements.

f1 Always uses VNA internal source 1.

f2 Select a source to be used for the f2 tone. This selection is available when an external source is configured and the Active box is checked on the External Source Configuration dialog.

Buttons

Add Source Click to configure an external source using the External Source Configuration dialog.

Path Configuration Click to launch the Path Configuration dialog (PNA-X models only).

How to add IMD Parameters

Using Hardkey/SoftTab/Softkey
1. Press Trace, then select trace.
2. Press Meas, then select a parameter.

Using a mouse
1. Click Instrument, Trace, Add Trace.
2. Click Response, Meas, then select a parameter.

IMD New Trace dialog box help
Use this dialog to select IMD and IMDx parameters to measure and display.

Up to five parameters can be selected at a time, then click **Apply** to create those traces. Then select more without closing the dialog. There is no limit to the number of traces and windows allowed in the VNA.

**Note:** Calculations are NOT performed to determine if the frequency of a selected intermod (Order) product will be within the frequency range of the VNA. Measurements that fall outside of the frequency range of the VNA are displayed as -200 dB.

**Param Name** This name is built from the selected **Type**, **Tone Select**, **Order**, and **Measure At** settings. Once built, check to measure this parameter.

**Type**

Select the type of Swept IMD measurement to make.

The characters below (in parenthesis) are used in the Param Name.

- **Tone Power (Pwr)** Measures the absolute power of the specified (ordered) tone. [Learn more.](#)

- **IMD Relative to Carrier (IM)** Measures the power of the specified (ordered) tone relative to the power of the f1 or f2 tone. [Learn more.](#)

- **Input Referred Intercept Point (IIP)** From DUT measurements, calculates the theoretical power level at which the specified (ordered) intermod product will be the same power level as the carrier at the output of
the DUT. The input power to the DUT at which this output power occurs is reported and displayed. Learn more.

- **Output Referred Intercept Point (OIP)** From DUT measurements, calculates the theoretical power level at which the specified (ordered) product will be the same power level as the main tone at the output of the DUT. This value is reported and displayed. Learn more.

- **CTB Band-Edge Distortion (CTBE)** Composite 'Triple Beat' Distortion - 3rd order DUT OUT only. Learn more.

- **CTB Mid-Band Distortion (CTB)** Composite 'Triple Beat' Distortion - 3rd order DUT OUT only. Learn more.

- **CSO Distortion (CSO)** 2nd order DUT OUT only. Learn more.

- **XMOD 3rd Order Crossmod (XMOD)** 3rd order DUT OUT only. Learn more.

- **Tone Gain (ToneGain)** From tone power measurements, calculates the Output Tone power / Input Tone power for the specified tones. Learn more. The Input and Output tones are different frequencies.

**Tone Select**

Select the tone (High, Low, or Both) to be measured and displayed (See image).

- **High** Measure and display the power of the specified (ordered) tone on the High side of the main tones.

- **Low** Measure and display the power of the specified (ordered) tone on the Low side of the main tones.

- **Avg** Measure the specified (ordered) tones on both the High and Low sides. Then calculate and display the Average power level. **Note:** The Avg power level is actually the mean dB value of the high and low side tones - NOT the true average power level which would be calculated from linear power (watts). This is done to be consistent with the Power Leveling algorithm that is used to set the tone powers equal at the DUT input or output, which is also based on the dB values.

- **Max** Measure the specified (ordered) tones on both the High and Low sides. Then find and display the Maximum power level.

- **Min** Measure the specified (ordered) tones on both the High and Low sides. Then find and display the Minimum power level.

Used to build the parameter name:

- **Hi, Lo, Max, and Min** are appended to the Param Name when selected.

- **Nothing is appended to the Param Name when Avg (default setting) is selected.**
### Important Notes - 2nd-order products

- 2nd-order products are likely to be outside of the VNA frequency range. When that occurs, trace data will show **all zeros** (linear) or **-200 dB** (log magnitude).
- If either the High or Low side falls outside the frequency range of the VNA, then **Avg** is NOT allowed.
- When displaying 2nd-order traces, **Avg** is NOT allowed, even when both the Lo and Hi products are displaying valid data. This is because 2 Low and 2 High products are usually very different from one another.
- When performing a calibration that is meant to include 2nd-order products, be sure **Include 2nd Order Products** is checked in the first Calibration dialog box.

### Order

Specify the intermodulation product to measure. Choose from 1, 2, 3, 5, 7, 9.

- **Main** is appended to the Param Name when 1 is selected.
- Otherwise, the tone number is appended to the parameter name.

### Measure At

Measure the selected parameter at either:

**DUT Input**

- **In** is appended to the Param Name (ex: PwrMainIn).
- The **input port reference receiver** is used to measure the fundamental tones and the required products.

**DUT Output**

- Nothing is appended to the Param Name (ex: PwrMain).
- The **output port measurement receiver** is used to measure the fundamental tones and the required products.
1. At the first page of the IMD Cal Wizard, you tell the calibration routine the frequencies at which the calibration is to be performed. Optionally, you can choose to perform the source power cal at only the center frequency midway between the main tones. For IMDx ONLY, you can also choose to perform a source power cal of the LO source.

2. The VNA calculates an array of source and receiver frequencies that incorporate all the main tone frequencies (low and high) and the specified product tone frequencies.

3. Using a power meter at port 1, a source and receiver calibration is performed to calibrate the R1 reference receiver to be a fast and ‘tunable’ power meter.

4. The R1 reference receiver is then used to perform a source power cal of the main tone frequencies: first the Source 1 / Low tone then the Source 2 / High tone. Both sources are left ON while each tone is measured in order to duplicate the impedance match under which the measurement will be performed.

5. Then a standard 2-port SOLT cal is performed at all frequencies using either an ECal module or mechanical standards. The 2-port cal is used to correct the source calibration R1 tracking terms for the match of the power sensor. It is also used to transfer the R1 tracking term to the B receiver.

Notes

- If the main tone frequencies change but are within the frequency range in which the calibration was performed, then the calibration becomes interpolated C*. This can occur by changing the start/stop/center/span frequencies, the number of points, or the sweep type. Learn more about Interpolation.

- A Preference setting can be made which allows a Swept IMD and IMDx calibration to exceed the stop frequency limit of an ECal module. Learn more.

- Receiver calibrations that are performed in a standard channel can be applied to a Swept IMD channel. However, Source Calibrations can NOT be applied.

See Also

IM Spectrum Calibration

How to start a Swept IMD Calibration

Using Hardkey/SoftTab/Softkey

1. Press CAL > Main > Smart Cal....

Using a mouse

1. Click Response
2. Select Cal
3. Select Smart Cal...
Select Tone Products - IMD Cal dialog box help

Calibration Mode

Match corrected Response Cal  This selection performs a full IMD calibration as described in the above Calibration 'Overview'.

**Response ONLY (Normalization)**  This IMD Cal does NOT correct for the mismatch of the power sensor. Choose this if you have a test configuration that does not easily accommodate making match measurements. Instead of a standard 2 port SOLT cal (Step 5 above), only the transmission tracking term is measured and used to transfer the R1 receiver tracking term (produced by the power sweep) to the B receiver.

**Note:** For the Response (Normalization) Cal, it is assumed that a zero-length THRU standard is being used to connect port 1 to port 2. If an adapter is used, there is NO compensation for delay or loss of the adapter. This can NOT be changed.

Tone Power Cal

**Calibrate only at center frequencies**  The source power cal portion is performed at only the center frequency, which is midway between the main tones. This cuts the source power calibration time (the slowest part of the calibration) in half. The measurement is interpolated although the C* annotation is not shown in the status bar.

**Calibrate at all frequencies**  The source power cal portion is performed at all main tone frequencies.

**Enable LO Power Calibration**  (IMDx ONLY) Check to perform a standard power calibration of the LO source as part of the calibration process.

Select Product Tones

**Max Product**  Select the highest product that you will be measuring. The low and high frequencies for that product, and all lower 'odd' order products will be calibrated. For example,
when 5th Order Product is selected, the frequencies for the Main Tones, and the Low and High order products for the 3rd and 5th order products will be included in the calibration.

**Include 2nd Order Products** Check to calibrate the 2nd-order products in the frequencies to be calibrated. The frequencies of these products are usually far from the main tones.

**Extrapolated ECal Calibration**

A *Preference setting* can be made which allows a Swept IMD and IMDx calibration to exceed the stop frequency limit of an ECal module. The error terms beyond the ECal stop frequency are extrapolated.

The setting is designed to provide correction for order products (especially 2nd order) when the frequencies exceed the ECal module stop frequency.

- The accuracy of the extrapolated error terms is not as good as those that were measured.
- This feature is NOT allowed when using *Cal All Channels*.
- The ECal Extrapolation state and frequencies are saved to the Cal Set and visible in the Cal Set Properties dialog.

---

**Select DUT Connectors and Cal Kits - IMD Cal dialog box help**

If *Response Only* is selected on the previous page, click **Source Cal Settings...** to change the Source Cal settings, or click **Next>** to continue.
Otherwise, this is a standard VNA Cal Wizard page except for the following:

**Modify Cal**  Check, then click **Next**, to Modify Cal (Standards AND Thru Method).

**Source Cal Settings**  Click to launch the **Source Cal Settings** (for Apps) dialog.

---

**Power Cal Settings - IMD Cal** dialog box help

A power calibration is performed on port 1. This is done to simplify subsequent IMD calibrations since the power calibration will not need to be repeated.

For highest accuracy, connect the power sensor directly to the test port with no adapter.

Learn more about these settings.
**IMD Calibration Step 1** dialog box help

**Power Level** at which to perform the Port 1 Source Power Cal.

It is usually best to perform the Source Power Cal at 0 dBm because the power sensor is calibrated at that level.

However, if a component is used between the VNA source and the calibration reference plane, then adjust the power level so that the power at the sensor is about 0 dBm if possible.

Learn more about IMD Calibration

The remaining dialog pages are the same as the standard Cal Wizard.

**Saving Swept IMD Power Data**

Swept IMD power data, Log Mag ONLY, can be saved to a *csv file. This data type can be read by spreadsheet programs, such as Microsoft Excel. Data from the last complete sweep is saved to the specified *csv file.

**How to save Swept IMD (and IMDx) data**

With a Swept IMD or IMDx channel active...

Using **Hardkey/SoftTab/Softkey**

1. Press **Save Recall** > **Save Other** > **Save Data**...  
2. File Type= CSV Formatted Data (*.csv).

Using **a mouse**

1. Click **File**  
2. Select **Save Data**  
3. File Type= CSV Formatted Data (*.csv).

**Notes:**
- For every tone, six power levels are saved in this order: OUT Avg | OUT Lo | OUT Hi | IN Avg | IN Lo | IN Hi
- Power levels for the Main tones are always saved, regardless of the active measurement.
- All tones that are displayed are also saved. For example, any displayed 3rd order tone parameter causes the 3rd tone power levels to be saved.
- Only tone powers are saved. Calculated parameters, such as IMD Relative to Carrier (IM) are NOT saved.
- If calibration is turned ON when the file is saved, then all data is calibrated. Otherwise, raw data is saved.

This image shows the 6 Main tone power levels that are always saved.

In the power parameter labels, Output and Avg are implied as in the parameter selection. For example: PwrMain = Average Output power of the main tones.
Intermodulation Spectrum measurements can be made independently, or coupled with Swept IMD measurements. They are a distinct measurement class. Therefore, IM Spectrum measurements are always made in a separate channel.

- Limitations

- Create an IM Spectrum Channel

- Select IM Spectrum Parameters

- Start the IM Spectrum Setup dialog
  - Frequency tab
  - Power tab
  - Tracking tab
  - Configure tab

- Calibration

See Also

- IM Spectrum Concepts
- IMx Spectrum for Converters
- Swept IMD Measurements
- Programming commands

Limitations with IM Spectrum

The following VNA features are NOT available in an IM Spectrum channel:

- Unratioed receiver measurements (A, B, R)
- ECal User Characterization
- FOM or FCA
- Time Domain
- Balanced measurements
- Save Formatted Citifile data.
- Save SnP data.
- External sources
- External Test Set Control (Option S93551A/B)
- Port Extensions
- Integrated Narrowband or Narrowband Pulse App
- DC Meter parameters
- Option 205 or Option 425

Create an IM Spectrum Channel

An IM Spectrum channel can be created independently from a Swept IMD channel or coupled with the stimulus settings of an existing Swept IMD measurement.

To create an independent IM Spectrum channel

1. Press **Meas > S-Param > Meas Class**.
2. Select **IM Spectrum**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

To create an IM Spectrum channel from an existing Swept IMD channel

1. With a Swept IMD channel active, press **Marker** on the front panel.
2. Move the marker to the data point of interest. It can be moved later.
3. Press **Marker > Marker Functions > Marker -> IM Spectrum**.

This creates or configures an existing IM Spectrum channel based upon the configuration of the Swept IMD channel.
To perform this function remotely:

Execute the VBScript file located on the VNA.

1. Create a macro. Either send this command or it can be done manually:
   `SYST:SHOR10:PATH "C:\Program Files (x86)\Keysight\Network Analyzer\Applications\IMD\imd.vbs"`

2. Execute the macro using: `SYST:SHOR10:EXEC` or the equivalent COM command: Execute Shortcut Method

Notes:

- 10 is the macro number. If you are already using this number for a macro, it will be overwritten.
- The marker must already be on the IMD trace and be the active marker.
- The path name to imd.vbs may be different on your VNA.

Select IM Spectrum Parameters

How to add IM Spectrum traces

With the IM Spectrum channel active and a Tr1 Output trace displayed:

Using Hardkey/SoftTab/Softkey

1. Press Trace, then select trace.
2. Press Meas, then select a parameter.

Using a mouse

1. Click Instrument, Trace, Add Trace.
2. Click Response, Meas, then select a parameter.

New Trace - IM Spectrum - dialog box help

Choose from:

- **Output Spectrum** View signals OUT of the DUT and into VNA port 2 (B receiver).
- **Input Spectrum** View signals IN to the DUT (R1 receiver). Use this when measuring IM product frequencies to determine the power level of spurious signals into the DUT at those frequencies.
- **Reflection Spectrum** View signals reflected off the DUT input and back into VNA port 1 (A receiver)
IM Spectrum Setup Dialog

How to start the IM Spectrum Setup dialog

With an IM Spectrum measurement active:

Using Hardkey/SoftTab/Softkey

1. Press Sweep > Main > IMS Setup....

Using a mouse

1. Click Stimulus
2. Select IMS Setup...

Frequency tab - IM Spectrum dialog box help

![Image]

**Note:** The number of data points in an IM Spectrum channel = 3 * SPAN / ResBW. This can NOT be changed directly.

Configures the Sweep Type and frequency range for IM Spectrum measurements.

**Sweep Type**

Provides several methods to tune the IM Spectrum **receivers** (NOT stimulus) to view the power spectrum of arbitrary frequency ranges or various distortion products.

**Linear**  Allows the start/stop or center/span receiver frequencies to be set arbitrarily for f1 and f2. Enter the Response Settings below.

**2nd Order**  Couples the receiver frequency range to f1 and f2 to provide a convenient means of observing the spectrum surrounding ONLY the high-side 2nd order harmonic where Center = (f1 + f2), Span = 3 * (f2 – f1). **Note:** The center frequency is NOT set on the main tones.

**3rd Order**  Couples receiver frequency range to f1 and f2 to provide a convenient means of observing the spectrum surround the main-tones including the 3rd Order products where Center = (f1 + f2) / 2, Span = 4 * (f2 – f1).
**Nth Order** Couples receiver frequency range to \( f_1 \) and \( f_2 \), providing a convenient means of observing the spectrum surrounding the main-tones for an arbitrary span where \( \text{Center} = \frac{(f_1 + f_2)}{2} \), and \( \text{Span} = N \times (f_2 - f_1) \). This allows you to set the span arbitrarily, but have the center frequency track the main tone frequencies.

**Resolution BW**

The IM Spectrum channel utilizes a set of Gaussian filters instead of the standard VNA IF filters in order to provide similar behavior to traditional spectrum analyzers.

The comprehensive list of filters that are available for IM spectrum are: 3 MHz, 1 MHz, 600 kHz, 300 kHz, 150 kHz, 100 kHz, 60 kHz, 10 kHz, 3 kHz, and 1 kHz.

**Note:** The 10 kHz Res BW filter can generate image signals which are not a product of the DUT. You can verify the integrity of a questionable signal by switching to the 3 kHz or 60 kHz filter and looking for the image signal in the same location.

Not all of these filters are available for all measurements. Narrower filters are available for use with narrower frequency spans, and wider filters are available for wider spans.

**Stimulus Settings**

Allows configuration of the main-tone frequencies. Available ONLY when Tracking is OFF.

- \( fc \) (main-tone center frequency) = \( \frac{(f_1 + f_2)}{2} \)
- \( \Delta f \) (main-tone frequency separation) = \( f_2 - f_1 \)
- \( f_1 \) = Low-side main-tone frequency
- \( f_2 \) = High-side main-tone frequency

**Response Settings**

Allows configuration of the frequency range to sweep the receivers in terms of start/stop or center/span. Available for Linear sweep types ONLY.

- **Start Spectrum** = first frequency point of the power spectrum sweep
  - **Note:** The minimum **Start Spectrum** frequency that can be set is 40 MHz.
- **Stop Spectrum** = last frequency point of the power spectrum sweep
- **Center Spectrum** = \( \frac{(\text{Start Spectrum} + \text{Stop Spectrum})}{2} \)
- **Span Spectrum** = (Stop Spectrum – Start Spectrum)

---

### Power tab - IM Spectrum - dialog box help

![Power tab screenshot]

Learn about this dialog

---

### Tracking tab - IM Spectrum - dialog box help

![Tracking tab screenshot]

These selections are NOT available when there is no Swept IMD channel.

Allows the IM Spectrum channel to use (track) the **stimulus** (Main Tone) settings of an existing Swept IMD channel.

**Tracking Enable**  Check to use the frequency and power stimulus settings from the specified IMD channel. When enabled, stimulus settings on the Frequency Tab are disabled and ALL stimulus settings, such as frequencies, power and attenuator settings, and calibration, are copied from the Swept IMD channel to the IM Spectrum channel.
In the top Swept IMD window the main tones are swept from 4 GHz to 6 GHz with some specified delta F tone separation. The marker is on the center data point at 5 GHz.

The bottom IM Spectrum window center frequency is the same as the above marker: 5 GHz, but it has a much narrower frequency range of +/- 500 kHz. The IM Spectrum channel sets the receiver to see the two main tones, plus the third, fifth, and seventh-order products.

**Step Mode**

When tracking is enabled, set the method by which the IM spectrum measurement tracks the IMD channel.

**Manual Step** When selected, IM Spectrum measurements occur at only the specified IMD channel data point. **Stimulus Point** specifies the data point, by number, in the Swept IMD channel which has the stimulus settings to use for the IM Spectrum sweep.

**Automatic Step** When selected, causes the IM Spectrum channel to sequentially setup each of the stimulus conditions through which the Swept IMD channel sweeps the DUT. Each sweep of IM Spectrum is performed using the next set of stimulus conditions.

For example, in the above image, the first Swept IMD data point is at 4 GHz. The first IM
Spectrum sweep uses a center frequency of 4 GHz. The following IM Spectrum sweep would be at the second Swept IMD data point or 4.01 GHz, and so forth. After the last data point in the sweep is reached, the IM Spectrum channel begins again at the first Swept IMD data point. The only indication that Tracking is enabled is in Automatic mode, you can see the center frequency increment with each IM Spectrum sweep.

**Configure tab- IM Spectrum Setup - dialog box help**

To accommodate single-source VNA models, an external source can be used for the RF2 tone.

Learn how to configure an external source and combiner to make Swept IMD, IMDx, IM Spectrum, and IM Spectrum for Converters measurements.

**RF1** Always uses VNA internal source 1.

**RF2** Available for selection when an external source is configured and Active.

**Add Source** Click to configure an external source using the External Source Configuration dialog.

**Path Configuration** Click to launch the Path Configuration dialog (PNA-X models only).

**Calibration**

A calibration corrects the IM Spectrum source and receiver power level accuracy of the displayed Tones.

A calibration of the IM Spectrum channel is NOT performed using the Calibration wizard. An IM Spectrum channel is calibrated by applying a Cal Set in one of the following ways:

- A cal that was used on a Swept IMD channel. The Cal Set can be applied to the IM Spectrum channel using
the Manage Cal Sets dialog (Learn how) or from the Marker =>IM Spectrum softkey (Learn how). However, a Swept IMD channel with Sweep Type = Power Sweep can NOT be applied to a IM Spectrum channel. This is because a Cal Set for power sweep contains only a CW frequency and the IM Spectrum channel requires a swept frequency range. Zero Span is not supported in an IM Spectrum channel.

- A Source Power and Receiver Cal Set from a standard channel calibration. This can be a full calibration, but must include a source power cal for the source port (1) and receiver cal for the B receiver. Only one source can be corrected. Learn how to apply a standard Cal Set.

See Swept IMD Calibration
Conceptually, Swept IMD for Converters (IMDx) is like IMD for Amplifiers, except that there are two sets of products on the DUT output.
This image shows the simplest measurement configuration: the Input, LO, and Output are all CW frequencies.

- **DUT INPUT** - two fundamental tones (f1 and f2)
- **DUT LO** - a single frequency.
- **DUT OUTPUT** - two sets of frequencies

With IMDx, you can view EITHER the High side or Low side products; NOT BOTH.

Make this selection on the **Mixer Frequency tab**.

- High side (Input **PLUS** LO and all ordered products)
- Low side (Input **MINUS** LO and all ordered products)

### Requirements and Limitations

Swept IMDx requires **Swept IMD** (Opt S93087A/B).

- When using **Integrated Pulse application**, the IF Filter setting for the relevant receiver must be changed to 'Wide'. Learn how. The default IF Filter setting in Swept IMD is 'Narrow' in order to avoid spurs and harmonics. The IF Attenuator setting (on the same dialog) may also require adjusting.

The following VNA features are **NOT** available with Swept IMDx:

- Analog Sweep (**Stepped sweep** mode only)
- **Log frequency** sweeps
- **Unratioed receiver measurements** (A, B, R)
- **ECal User Characterization**
- **Time Domain**
- **Balanced measurements**
- **Save Formatted Citifile data.**
- **Save SnP data.**
- **Port extensions**
- **Some Fixturing Features**
• External Test Set Control (Option S93551A/B)

• Integrated Narrowband or Narrowband Pulse App

• Independent IFBW, Power Levels, or Sweep Time in a segment table is NOT supported.

• External DC Sources (DC Meters ARE supported).

• See Frequency Limitations

• Option 205 or Option 425

**Note:** Beginning with A.09.00, **Embedded LO** measurements are allowed in IMDx and IMSpectrum. Configure the measurement as you would with SMC. Learn how.

### How to Configure your Hardware

The VNA is extremely versatile, and can be configured in many ways to make IMDx measurements. While not all conceivable configurations are documented here, a few of the most common examples are provided to show the basic concepts.

#### DUT Configuration

- The DUT Input must be connected to VNA Port 1 which supplies the f1 and f2 tones.
- The DUT Output must be connected to VNA Port 2 which uses the VNA B receiver.
- See LO Source configuration below.

#### Source Configuration

Three sources are required to make IMDx measurements: Two sources are VNA internal; the third is an external source.

- **F1 tone** - Must come out VNA Port 1 Default is Src 1
- **F2 tone** - Must come out VNA Port 1 through the internal combiner. This source can come from an internal or external source. Default is the internal Src 2.
- **LO** - Can come from internal or external source. Default is Not controlled, set to 0 Hz.

  - If using the internal Src 2 source, the f2 tone must come from an external source through the rear-panel.
If using an external source, it can be connected directly to the DUT, or through the VNA Port 3 or Port 4 using the Path Configurator.

**Configuration Examples**

Three configurations are shown below to illustrate how to use the Path Configurator to manually make switch settings.

IMDx and IMx Spectrum channels are ALWAYS configured using the default configuration switch settings shown in the image below. This is NOT the same default configuration that is used for an S-parameter channel. A manual switch setting is required whenever a custom configuration is used.

The manual switch setting, which must be done every time an IMDx or IMx Spectrum channel is created, can be saved using the Store button in the Path Configurator. Then save the entire IMDx setup as an Instrument State. This will load the custom Path Configuration when the Instrument State is recalled.

1. **Default Configuration**  No manual switching required.
   
   - **f1** - Internal Src1
   - **f2** - Internal Src2 through combiner in Normal
   - **LO** - Connect external source directly to the DUT LO.

2. **External LO though Port 3 or Port 4 (4-port VNA only)**

Use this configuration to monitor LO power using R3 or R4. (Future parameters)
- **f1** - Internal Src1
- **f2** - Internal Src2 through combiner in Normal
- **LO** - Connect external source through the rear-panel (J7 for Port 3; J3 for Port 4).
  - Connect the DUT LO to VNA Port 3 or Port 4.
  - For Port 3, NO switching is required.
  - For Port 4, switch Port 4 Bypass Switch to **Rear Panel**.

3. **Internal LO through Port 3 or Port 4; External f2 through rear-panel (4-port VNA only)**

   This configuration is commonly used for FCA measurements where the internal second source is used as the LO.

   - **f1** - Internal Src1
   - **f2** - External f2 through rear-panel J9. No switching required.
   - **LO** - Internal Src2 through:
     - Port 3  Switch Port 3 Bypass Switch to **Thru Path**. Connect the DUT LO to VNA Port 3
     - Port 4  Switch Port 4 Bypass Switch to **Thru Path**. Connect the DUT LO to VNA Port 4

### Create a Swept IMDx Measurement

1. Press **Meas > S-Param > Meas Class....**

2. Select **Swept IMD Converters**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

3. A Swept IMDx measurement is displayed. To select additional parameters to display, click **Response**, then **Measure**, then select a parameter from the list.
How to start the Swept IMDx Setup dialog

Using **Hardkey/SoftTab/Softkey**

1. Press  **Freq > Main > IMDX Setup...**

Using a mouse

1. Click  **Stimulus**
2. Select  **IMDX Setup...**

### Programming Commands

---

**Valid Mixer Configuration / Sweep Type Combinations**

#### Tips

Although you will soon become comfortable navigating these tabs, at first it may be best to complete the dialog in the following order:

1. On the **Tone Frequency tab**, set the Sweep Type and Tone Frequencies.
2. On the **Mixer Frequency tab**, set a valid mixer configuration.

- Input center / fixed frequency CAN be set on both the **Tone Frequency tab** and the **Mixer Frequency tab**. When you set one, the other is updated automatically.

---

The following are the **Valid Mixer Configurations** in table format:

<table>
<thead>
<tr>
<th>Sweep Type</th>
<th>Input</th>
<th>LO</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Swept Input (Fixed Tones)</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sweep fc</td>
<td>Swept</td>
<td>Swept</td>
<td>Fixed</td>
</tr>
<tr>
<td></td>
<td>Swept</td>
<td>Fixed</td>
<td>Swept</td>
</tr>
<tr>
<td><strong>All Ranges Fixed</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CW</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sweep Delta F</td>
<td>Fixed</td>
<td>Fixed</td>
<td>Fixed</td>
</tr>
<tr>
<td>(Tone) Power Sweep</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>LO Power Sweep</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Fixed Input / Swept LO &amp; Output</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CW</td>
<td>Fixed</td>
<td>Swept</td>
<td>Swept</td>
</tr>
</tbody>
</table>
For determining a valid mixer configuration with 2 LOs, one Fixed LO and one Swept is equivalent to having a single-stage Swept LO.

If you create an invalid Sweep Type / Mixer Configuration, a red message appears like the following:

**ERROR: Input range must be swept in Linear sweep mode.**

- If this occurs, change the **Sweep Type** on the Tone Frequency tab.
- See other rules for configuring a mixer.
- The following is an explanation of the table:

**SWEPT Input** - Sweeps the center frequency of the tones, but the tone spacing remains fixed.

On the Tone Frequency tab, select **Sweep fc**

- Either the LO or Output MUST also be swept.
- On the Mixer Frequency tab, select Start/Stop, or Center/Span for each range to be swept.

**FIXED Input** - The center frequency of the tones is fixed.

On the Tone Frequency tab select **Fixed** for the following sweep type:

- **CW** - Tones do NOT change. The LO and Output frequencies CAN be swept.

**All Ranges FIXED** - The center frequency of the tones is fixed.

On the Tone Frequency tab select **Fixed** for the following sweep types:

- **Sweep Delta F** - Tone separation changes.
- **Power Sweep** - Tone power changes.
- **LO Power Sweep** - The LO power is swept.
- **CW** - Tones do NOT change.

**Setup Dialog**

The following tabs are shared with the Swept IMD Setup dialog:

- **Tone Frequency tab**
• Tone Power tab

The following tabs are shared with all Mixer / Converter Applications

• Mixer Frequency tab

How to add Swept IMDx Parameters

Using Hardkey/SoftTab/Softkey

1. Press Trace, then select trace.
2. Press Meas, then select a parameter.

Using a mouse

1. Click Instrument, Trace, Add Trace.
2. Click Response, Meas, then select a parameter.
This dialog is shared with Swept IMD for Amplifiers.

Learn about this dialog.

**IMDx Calibration**

Calibration for IMDx is exactly the same as calibration for IMD with the following exception:

- You can choose to perform a source power cal of the LO source. If the LO is a fixed frequency, this step is performed very fast.

The results of an IMDx calibration are very similar to the results that are achieved from an SMC calibration.
IMx Spectrum for Converters

IMx Spectrum measurements are a distinct measurement class and therefore always made in a separate channel. This topic discusses all aspects of an IMx Spectrum measurement.

- Limitations
- How an IMx Spectrum Channel Works
- Create an IMx Spectrum Channel
- Select IMx Spectrum Parameters
- Start the IMx Spectrum Setup dialog
  - Frequency tab
  - Tone Power tab
  - Mixer Frequency tab (separate topic)
  - Mixer Power tab (separate topic)
  - Mixer Setup tab
- Calibration

See Also

- Swept IMD Measurements
- Programming commands

Limitations

IMx Spectrum requires IMD (Opt S93087A/B).
Note:

The **minimum** frequency of this application is **40 MHz**. (10 MHz plus 30 MHz).

The **maximum** frequency of this application is the MAX frequency of the VNA **MINUS 30 MHz**.

This is due to the use of the various IF frequencies.

The following VNA features are NOT available in an IMx Spectrum channel:

- Unratioed receiver measurements (A, B, R)
- ECal User Characterization
- FOM or FCA
- Time Domain
- Balanced measurements
- Save Formatted Citifile data.
- Save SnP data.
- External sources
- External Test Set Control (Option S93551A/B)
- Interface Control
- Port Extensions
- Fixturing Simulator
- Integrated Narrowband or Narrowband Pulse App
- Option 205 or Option 425

**Note:** Opt S93084A/B (**Embedded LO measurements**) is NOT necessary to make an IMx Spectrum measurement on converters with an embedded LO. This is because the embedded LO can be slightly off-frequency and the output tones will still be visible on the IMxSpectrum display. You may have to select **Linear** sweep type, then set the response frequency span wide enough to allow for a more off-frequency embedded LO. **Learn how.**
How an IMx Spectrum for Converters Channel Works

Before reading this topic, you should become familiar with IMD Concepts.

The IMx Spectrum channel provides a traditional Spectrum Analyzer view of the intermodulation distortion behavior of a converter output. Unlike the Swept IMDx channel, the main tones (F1 and F2) are fixed while the receiver is swept over a frequency range of interest in order to generate a display as shown below.

A typical Spectrum Analyzer does NOT have a signal source. This one does. The signal source, or stimulus, settings for the F1 and F2 main tones can be set in either the IMx Spectrum channel or the Swept IMDx channel. These settings include the frequencies and power levels of the main tones.

**Receiver Settings**

Although the stimulus settings can be set in either the IMx Spectrum channel or the Swept IMDx channel, the receiver settings are set ONLY in the Frequency tab of the IMx Spectrum dialog. These settings include how many tone products to view, which determines the center and frequency span and the resolution bandwidth. You can also set a Linear sweep type, then enter an arbitrary receiver frequency range.

You can choose from several resolution bandwidths which also determines the number of data points used in the channel. The higher the Res BW, the fewer the number of data points.

The IMx Spectrum channel performs multiple measurements for each data point in order to reject
unwanted images which are generated by the VNA internally. This provides a high degree of confidence that signals captured in a trace are real and are not spurious responses generated in the measurement process.

**Differences from IM Spectrum for Amplifiers**

An IMx Spectrum for Converters channel has the following important differences from an IM Spectrum channel for Amplifiers.

- In an IMx Spectrum channel, **all converter frequencies are fixed**. (Input, Output, LO, Tone Spacing, and Tone Power).

- The IMx Spectrum channel **CANNOT track** with the IMDx channel, as it can in IMD for Amplifiers.

**Create an IMx Spectrum Channel**

An IMx Spectrum channel can be created independently, or from an existing Swept IMDx channel.

**To create an independent IMx Spectrum channel**

1. Press **Meas > S-Param > Meas Class....**

2. Select **IMx Spectrum**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

**To create an IMx Spectrum channel from an existing Swept IMD channel**

This creates or configures an existing IMx Spectrum channel based upon the configuration of the Swept IMD channel at the Marker frequency.

1. With a Swept IMD channel active, press the **Marker** key on the front panel.

2. Move the marker to the data point of interest. It can be moved again later.

3. Press **[Marker Functions]** then **[Marker -> IMx Spectrum]**

**Select IMx Spectrum Parameters**
How to add IMx Spectrum traces

With the IMx Spectrum channel active and a Tr1 Output trace displayed:

Using **Hardkey/SoftTab/Softkey**

1. Press **Trace**, then select trace.
2. Press **Meas**, then select a parameter.

Using a mouse

1. Click **Instrument, Trace, Add Trace**.
2. Click **Response, Meas**, then select a parameter.

### New Trace - IMx Spectrum -dialog box help

To accommodate single-source VNA models, an external source can be used for the RF2 tone.

Learn how to configure an external source and combiner to make Swept IMD and IMDx measurements.

**Converter Stages** Choose from 1 or 2 stage DUT (# of LOs).

**Converter Model**

- **f1** Always uses VNA internal source 1.

- **(DUT Input) Port N** Available for selection on 4-port VNA models. Select the VNA port (1 or 3) to connect to the DUT Input.

- **f2** Available for selection when an external source is configured and Active.

- **LO1 (and LO2 for 2-stage DUTs)** Select the source to use for the specified LO. Available for selection when an external source is configured and Active.

- **(DUT Output) Port N** Available for selection on 4-port VNA models. Select the VNA port to connect to the DUT Output.

**Hardware Configuration**

- **Add Source** Click to configure an external source using the External Source Configuration dialog.

- **Path Configuration** Click to launch the Path Configuration dialog (PNA-X models only).

**Calibration**

A calibration of the IMx Spectrum channel is NOT performed using a calibration wizard.
An IMx Spectrum channel is calibrated from a Cal Set that is used on a Swept IMDx channel. The Cal Set can be applied to the IMx Spectrum channel using the Manage Cal Sets dialog (Learn how) or from the Marker =>IMx Spectrum softkey (Learn how).

However, a Swept IMDx channel with Sweep Type = Power Sweep can NOT be applied to a IMx Spectrum channel. This is because a Cal Set for power sweep contains only a CW frequency and the IMx Spectrum channel requires a swept frequency range. Zero Span is not supported in an IMx Spectrum channel.

A calibrated IMx Spectrum trace corrects the source and receiver power level accuracy of the displayed Tones.

See Swept IMD Calibration

Learn how to apply a Cal Set to the IMx Spectrum channel
Time Domain

Note: Time Domain measurements are only available on analyzers with S9x010A. See Configurations.

Time Domain allows you to view a device response as a function of time. The following are discussed in this topic:

- Overview
- How the Analyzer Measures in the Time Domain
- Calibration for Time Domain
- Transmission Measurements
- Measurement Response Resolution
- Measurement Range and Alias Responses
- How to make Time Domain Settings
- Gating
- Advanced Settings

See the updated App Note: Time Domain Analysis Using a Network Analyzer.

Overview

In normal operation, the analyzer measures the characteristics of a test device as a function of frequency. With Time Domain (opt S9x010A), the frequency information is used to calculate the inverse Fourier transform and display measurements with time as the horizontal display axis. The response values appear separated in time, allowing a different perspective of the test device's performance and limitations.

The graphic below compares the same cable reflection measurement data in both the frequency and time domain. The cable has two bends. Each bend creates a mismatch or change in the line impedance.
The frequency domain S11 measurement shows reflections caused by mismatches in the cable. It is impossible to determine where the mismatches physically occur in the cable.

The time domain response shows both the location and the magnitude of each mismatch. The responses indicate that the second cable bend is the location of a significant mismatch. This mismatch can be gated out, allowing you to view the frequency domain response as if the mismatch were not present. Distance Markers can be used to pinpoint the distance of the mismatch from the reference plane.

How the Analyzer Measures in the Time Domain

Time domain transform mode simulates traditional Time-Domain Reflectometry (TDR), which launches an impulse or step signal into the test device and displays the reflected energy on the TDR screen. By analyzing the magnitude, duration, and shape of the reflected waveform, you can determine the nature of the impedance variation in the test device.

The analyzer does not launch an actual incident impulse or step. Instead, a Fourier Transform algorithm is used to calculate time information from the frequency measurements. The following shows how this occurs.

A single frequency in the time domain appears as a sine wave. In the following graphic, as we add the fundamental frequency (F0), the first harmonic (2F0), and then the second harmonic (3F0), we can see a pulse taking shape in the Sum waveform. If we were to add more frequency components, the pulse would become sharper and narrower. When the analyzer sends discrete frequencies to the test device, it is in effect, sending individual spectral pieces of a pulse separately to stimulate the test device.

During an S11 reflection measurement, these incident signals reflect from the test device and are measured at the A receiver. This is when the time domain transform calculations are used to add the separate spectral pieces together.
For example, consider a short length of cable terminated with an open. All of the power in the incident signal is reflected, and the reflections are 'in-phase' with the incident signal. Each frequency component is added together, and we see the same pattern as the simulated incident would have looked (above). The magnitude of the reflection is related to the impedance mismatch and the delay is proportional to the distance to the mismatch. The x-axis (time) scale is changed from the above graphic to better show the delay.

Alternately, the same cable terminated with a short also reflects all of the incident power, but with a phase shift of 180 degrees. As the frequency components from the reflection are added together, the sum appears as a negative impulse delayed in time.

Calibration for Time Domain

For simplicity, we have discussed incident signals reflecting off discontinuities in the test device. By far the most common network analyzer measurement to transform to time domain is a ratioed S11 measurement. An S11 reflection measurement does not simply display the reflections measured at the A receiver - it displays the ratio (or difference) of the A receiver to the Reference receiver. In addition, the S11 measurement can also be calibrated to remove systematic errors from the ratioed measurement. This is critical in the time domain as the measurement plane, the point of calibration, becomes zero on the X-axis time scale. All time and distance data is presented in reference to this point. As a result, both magnitude and time data are calibrated and very accurate.

The following shows where the time domain transform occurs in the analyzer data flow: (see Data Access Map)
1. Acquire raw receiver (A and R1) data
2. Perform ratio (A/R1)
3. Apply calibration
4. Transform data to time domain
5. Display results

Therefore, although a time domain trace may be displayed, a calibration is always performed and applied to the frequency domain measurement which is not displayed.

Transmission Measurements

The most common type of measurement to transform is an S11 reflection measurement. However, useful information can be gained about a test device from a transformed S21 transmission measurement. The frequency components pass through the test device and are measured at the B receiver. If there is more than one path through the device, they would appear as various pulses separated in time.

For example, the following transmission measurement shows multiple paths of travel within a Surface Acoustic Wave (SAW) filter. The largest pulse (close to zero time) represents the propagation time of the shortest path through the device. It may not be the largest pulse or represent the desired path. Each subsequent pulse represents another possible path from input to output.

![Transmission Measurement Diagram](image)

Triple travel is a term used to describe the reflected signal off the output, reflected again off the input, then finally reappearing at the output. This is best seen in a time domain S21 measurement.

Measurement Response Resolution

In the previous paragraphs, we have seen that using more frequency components causes the assembled
waveform to show more detail. This is known as measurement response resolution, which is defined as the ability to distinguish between two closely spaced responses.

**Note:** Adjusting the *transform time settings* improves *display* resolution, but not measurement resolution.

The following graphic shows the effect of both a narrow and wide frequency span on the response resolution. The wider frequency span enables the analyzer to resolve the two connectors into separate, distinct responses.

**Resolution Formula**

For responses of equal amplitude, the response resolution is equal to the 50% (-6 dB) points of the impulse width, or the step rise time which is defined as the 10 to 90% points as shown in the following image.

The following table shows the *approximated* relationship between the frequency span and the window selection on response resolution for responses of equal amplitude.
<table>
<thead>
<tr>
<th>Window</th>
<th>Low-pass step (10% to 90%)</th>
<th>Low-pass impulse (50%)</th>
<th>Bandpass impulse</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum</td>
<td>0.45 / f span</td>
<td>0.60 / f span</td>
<td>1.20 / f span</td>
</tr>
<tr>
<td>Normal</td>
<td>0.99 / f span</td>
<td>0.98 / f span</td>
<td>1.95 / f span</td>
</tr>
<tr>
<td>Maximum</td>
<td>1.48 / f span</td>
<td>1.39 / f span</td>
<td>2.77 / f span</td>
</tr>
</tbody>
</table>

For example, using a 10 GHz wide frequency span and a normal window in Bandpass impulse mode, response resolution (in time) equals:

- Time Res = 1.95 / frequency span
- Time Res = 1.95 / 10 GHz
- Time Res = 195 ps

To calculate the physical separation (in distance) of the responses which can be resolved, multiply this value times the speed of light (c) and the relative velocity (Vf) of propagation in the actual transmission medium. In this case, Vf = 0.66 for polyethylene dielectric.

- Distance Res = 195 ps x c x Vf
- Distance Res = 195 ps x (2.997925 E8 m/s) x .66
- Distance Res = 38 mm

For reflection measurements, because of the 2-way travel time involved, this means that the minimum resolvable separation between discontinuities is half of this value or 19 mm.

Although a wider frequency span causes better measurement resolution, the measurement range becomes limited. Also, increasing the frequency range can cause a measurement calibration to become invalid. Be sure to adjust the frequency span BEFORE performing a calibration.

**Measurement Range and Alias Responses**

Measurement range is the length in time in which true time domain responses can be seen. The measurement range should be large enough to see the entire test device response without encountering a repetition (alias) of the response. An alias response can hide a true time domain response.

To increase measurement range in both modes, change either of these settings:

- Increase the number of points
• Decrease the frequency span

Notes:

• After making these settings, you may need to adjust the transform time settings to see the new measurement range.
• Decreasing the frequency span degrades measurement resolution.
• Make frequency span and number of points settings BEFORE calibrating.
• Maximum range also depends on loss through the test device. If the returning signal is too small to measure, the range is limited regardless of the frequency span.

Alias Responses

An alias response is not a true device response. An alias response repeats because each time domain waveform has many periods and repeats with time (see How the Analyzer Measures in the Time Domain). Alias responses occur at time intervals that are equal to 1/frequency step size.

The analyzer adjusts the transform time settings so that you should only see one alias free range on either side (positive and negative) of zero time. However, these settings are updated only when one of the toolbar settings are changed.

To determine if a response is true, put a marker on the response and change the frequency span. A true device response will not move in time. An alias response will move.

For example, in the above graphic, the marker 1 response occurs at 14.07 inches. When the frequency span is changed, this response remains at 14.07 inches. The marker 2 response moves.

Range Formula

You can calculate the alias-free measurement range (in meters) of the analyzer using the following
formula for TDR (reflection) measurements:

**Range (meters) = \( (1/\Delta f) \times V_f \times c \)**

Where:

- \( \Delta f \) = frequency step size (frequency span/number of points-1)
- \( V_f \) = the velocity factor in the transmission line
- \( c \) = speed of light = 2.997925 E8 m/s

For example: For a measurement with 401 points and a span of 2.5 GHz, using a polyethylene cable (\( V_f = 0.66 \))

- Range = \( (1 / (2.5E9 / 400)) \times 2.997925 \times 0.66 \)
- Range = 6.25E6 \times 2.997925 \times 0.66
- Range = 32 meters

In this example, the range is 32 meters in physical length. To prevent the time domain responses from overlapping or aliasing, the test device must be 32 meters or less in physical length for a transmission measurement.

To calculate the one-way distance for a reflection measurement rather than round-trip distance, simply divide the length by 2. In this case, the alias-free range would be 16 meters.

### How to make Time Domain Settings

**Using Hardkey/SoftTab/Softkey**

1. Press **Math > Time Domain > Time Domain Setup....**

### Transform dialog box help
Transform On  Turns time domain transform ON and OFF.

Time Settings

The following settings adjust the display resolution, allowing you to zoom IN or OUT on a response. They do NOT adjust measurement range or measurement resolution.

These settings automatically update (when one of these values are updated) to limit the display to one alias-free response on either side of zero time.

Start  Sets the transform start time that is displayed on the analyzer screen.

Note: Zero (0) seconds is always the measurement reference plane. Negative values are useful if moving the reference plane.

Stop  Sets the transform stop time that is displayed on the analyzer screen.

Center  Sets the transform center time that is displayed in the center of the analyzer screen.

Span  Sets the transform span time that is split on either side of the Center value.

Transform Mode

Transform modes are three variations on how the time domain transform algorithm is applied to the frequency domain measurement. Each method has a unique application.
<table>
<thead>
<tr>
<th>Mode</th>
<th>Benefit - application</th>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low pass Impulse</td>
<td>Highest resolution.</td>
<td>In both Low pass modes, frequencies down to DC and negative frequencies are extrapolated.</td>
</tr>
<tr>
<td></td>
<td>Most useful for seeing small responses in devices that pass low frequencies,</td>
<td>Therefore, the Start frequency is adjusted when you click Set Freq.Low Pass</td>
</tr>
<tr>
<td></td>
<td>such as cables.</td>
<td>Because this will affect calibration accuracy, be sure to calibrate AFTER completely setting up</td>
</tr>
<tr>
<td></td>
<td></td>
<td>your time domain measurement.</td>
</tr>
<tr>
<td>Low pass Step</td>
<td>Easiest to identify inductive and capacitive discontinuities in devices that pass</td>
<td></td>
</tr>
<tr>
<td></td>
<td>low frequencies, such as cables.</td>
<td></td>
</tr>
<tr>
<td>Band pass Impulse</td>
<td>Easiest method - can be used with any frequency sweep.</td>
<td>Does NOT show capacitive and inductive reactance</td>
</tr>
<tr>
<td></td>
<td>Most useful for measuring band limited devices such as filters and DC blocked cables.</td>
<td>For the same frequency span and number of points, band pass mode has twice the impulse width,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>which hides closely spaced responses degrading the response resolution.</td>
</tr>
</tbody>
</table>

The following chart shows how to interpret results from various discontinuity impedances using Low pass Step and either Low pass or Band pass Impulse modes.

</tbody>
</table>

**Effect on Measurement Range**

**Band pass mode** - measurement range is inversely proportional to frequency step size.
**Low pass mode** - measurement range is inversely proportional to the fundamental (start) frequency AFTER clicking Set Freq. Low Pass.

**Set Low Pass Frequencies** USE ONLY IN LOW PASS MODES

Recomputes the start frequency and step frequencies to be harmonics of the start frequency. Start frequency is computed by the following formula: **Low Pass Start Frequency = Stop Frequency / Number of points.**

The computed value must always be greater than or equal to the analyzer's minimum frequency.

**Note:** The number of points or stop frequency may be changed in order to compute this value.

**Gating**

Perhaps the most beneficial feature of time domain transform is the Gating function. When viewing the time domain response of a device, the gating function can be used to "virtually" remove undesired responses. You can then simultaneously view a frequency domain trace as if the undesired response did not exist. This allows you to characterize devices without the effects of external devices such as connectors or adapters.

**Note:** When a discontinuity in a test device reflects energy, that energy will not reach subsequent discontinuities. This can "**MASK**", or hide, the true response which would have occurred if the previous discontinuity were not present. The analyzer Gating feature does NOT compensate for this.

The following measurements images show a practical example how to use and perform gating. The test device is a 10 inch cable, then a 6 dB attenuator, terminated with a short. The following four discontinuities are evident in window 2, from left to right:

1. A discontinuity in the test system cable which appeared after calibration. It is identified by marker 2 at -10.74 inches (behind the reference plane).

2. A discontinuity in the 10 inch device cable shortly after the reference plane.

3. The largest discontinuity is the attenuator and short shown by marker 1 at -12.67 dB (6 dB loss in both forward and reverse direction).

4. The last discontinuity is a re-reflection from the device cable.

We will gate IN the attenuator response. All other responses will be gated OUT.

**Window 1.** Create original S11 frequency domain trace. Shows ripple from all of the reflections.
Window 2. Create a new S11 trace - same channel; new window. Turn Transform ON.

Window 3. On the transformed trace, turn gating ON. Center the gate on the large discontinuity (2.500ns). Adjust gate span to completely cover the discontinuity. Select Bandpass gating type.

Window 4. On the original frequency measurement, turn Gating ON (Transform remains OFF). View the measurement without the effects of the two unwanted discontinuities. The blue trace is a measurement of the 6 dB attenuator with the unwanted discontinuities PHYSICALLY removed. The difference between the two traces in window 4 is the effect of "masking".

Learn how to launch the Transform dialog box

Programming Commands

Transform Gating dialog box help
Gating  Turns Gating ON and OFF.

Start  Specifies the start time for the gate.

Stop  Specifies the stop time for the gate.

Center  Specifies the value at the center of the area that is affected by the gating function. This value can be anywhere in the analyzer range.

Span  Specifies the range to either side of the center value of area that is affected by the gating function.

Gate Type  Defines the type of filtering that will be performed for the gating function. The gate start and stop flags on the display point toward the part of the trace you want to keep.

- **Bandpass** - KEEPS the responses within the gate span.
- **Notch** - REMOVES the responses with the gate span.

Gate Shape  Defines the filter characteristics of the gate function. Choose from Minimum, Normal, Wide, Maximum
<table>
<thead>
<tr>
<th>Gate Shape</th>
<th>Passband Ripple</th>
<th>Sidelobe Levels</th>
<th>Cutoff Time</th>
<th>Minimum Gate Span</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum</td>
<td>±0.1 dB</td>
<td>-48 dB</td>
<td>1.4/Freq Span</td>
<td>2.8/Freq Span</td>
</tr>
<tr>
<td>Normal</td>
<td>±0.1 dB</td>
<td>-68 dB</td>
<td>2.8/Freq Span</td>
<td>5.6/Freq Span</td>
</tr>
<tr>
<td>Wide</td>
<td>±0.1 dB</td>
<td>-57 dB</td>
<td>4.4/Freq Span</td>
<td>8.8/Freq Span</td>
</tr>
<tr>
<td>Maximum</td>
<td>±0.01 dB</td>
<td>-70 dB</td>
<td>12.7/Freq Span</td>
<td>25.4/Freq Span</td>
</tr>
</tbody>
</table>

**Cutoff time** -- is the time between the stop time (-6 dB on the filter skirt) and the peak of the first sidelobe. The diagram below shows the overall gate shape and lists the characteristics for each gate shape.

- T₁ is the gate span, which is equal to the stop time minus the start time.
- T₂ is the time between the edge of the passband and the 6 dB point, representing the cutoff rate of the filter.
- T₃ is the time between the 6 dB point and the edge of the gate stopband.
- For all filter shapes T₂ is equal to T₃, and the filter is the same on both sides of the center time.

**Minimum gate span** -- is twice the cutoff time. Each gate shape has a minimum recommended gate span for proper operation. This is a consequence of the finite cutoff rate of the gate. If you specify a gate span that is smaller than the minimum span, the response will show the following effects:

- distorted gate shape that has no passband
- distorted shape
- incorrect indications of start and stop times
- may have increased sidelobe levels

To launch the Coupling dialog box, click Coupling tab on the Time Domain Setup dialog box.

**Programming Commands**

**Trace Coupling Settings** dialog box help
Trace coupling allows you to change time domain parameters on a measurement, and have the same changes occur for all other measurements in the channel.

For example:

If you are simultaneously viewing a frequency domain measurement and time domain measurement,

and **Coupling** is enabled in this dialog box,

and ALL **Gating Parameters** are checked in this dialog box,

and on the time domain measurement you change the **Gate Span** parameter,

Then the frequency domain measurement will automatically change to reflect the time domain gated span.

**Note:** Trace coupling applies ONLY to the Y-axis scale/reference settings. There are no changes to your data as a result of trace coupling.

**Coupling On** Check to enable coupling. All of the measurements in the active channel are coupled.

The following parameters are available for coupling:

**Transform Parameters**

- **Stimulus** Start, Stop, Center, and Span TIME settings.
- **State** (On/Off) Transform ON and OFF
Window  Kaiser Beta / Impulse Width

Mode  Low Pass Impulse, Low Pass Step, Band Pass

Gating Parameters

Stimulus  Start, Stop, Center, and Span TIME settings.

State  (On/Off)  Gating ON and OFF

Shape  Minimum, Normal, Wide, and Maximum

Type  Bandpass and Notch

To launch the Distance marker dialog box, click Dist. Marker Settings on the Transform dialog box.

Programming Commands

Distance Marker Settings  dialog box help

When markers are present on a time domain measurement, distance is automatically displayed on the marker readout, marker table, and print copy. To learn how to create markers on your measurement see marker settings.

You can read out impedance versus time by creating a marker on a Time Domain trace, then changing the marker format to R+jX. Learn how.
This dialog box allows you to customize the time domain distance marker readings.

These settings affect the display of ALL markers for only the ACTIVE measurement (unless **Distance Marker Unit** is coupled on the Trace Coupling dialog box.

**Marker Mode**  Specifies the measurement type in order to determine the correct marker distance.

- Select **Auto** for S-Parameter measurements.
- Select **Reflection** or **Transmission** for arbitrary ratio or unratioed measurements.

**Auto**  If the active measurement is an S-Parameter, automatically chooses reflection or transmission. If the active measurement is a non S-Parameter, reflection is chosen.

**Reflection**  Displays the distance from the source to the receiver and back divided by two (to compensate for the return trip.)

**Transmission**  Displays the distance from the source to the receiver.

**Units**  Specifies the unit of measure for the display of marker distance values.

**Velocity Factor**  Specifies the velocity factor that applies to the medium of the device that was inserted after the measurement calibration. The value for a polyethylene dielectric cable is 0.66 and 0.7 for PTFE dielectric. 1.0 corresponds to the speed of light in a vacuum. This is useful in Time Domain for accurate display of time and distance markers.

This setting can also be made from the Electrical Delay and Port Extensions dialog boxes.

---

**Advanced Settings**

**Programming Commands**
The following methods set window size. For best results, view the time domain response while making these settings.

- **Kaiser Beta** Changes window size using a Kaiser Beta value
- **Impulse Width** Changes window size using an Impulse Width value

**Transform Alignment**

**Alignment Type**

- **Legacy** - The DC value is extrapolated using three data points. The transform offset is calculated using the delay of the first frequency point. This is the same algorithm used in the HP 8510 network analyzer.

- **Normalize** - The DC value is extrapolated using three data points. The transform offset is set to zero at t=0 minus six rise-times. This mode requires that a good S-parameter calibration has been performed, which can be verified by observing a flat time-domain response at t=0 when measuring a load located at the physical point corresponding to t=0. Setting the time domain trace to zero at a time before t=0 stabilizes the trace for determining impedances after time t=0, resulting in improved behavior compared to Legacy mode. This method is similar to that used with PLTS, and is very useful in determining the time-domain-transform response of transmission lines and printed-circuit-board characteristics.

**Limit Start/Stop Times to Avoid Aliasing** - Check to limit the start/stop times to avoid aliasing.
How to launch the Time Domain Toolbar

Features and Limitations

Features

The TDR option (S9x011A/B) provides the following features:

- Up to 67 GHz of bandwidth with 6.66 ps (10%-90%) or 4.73 ps (20%-80%) rise time enables measurement on the latest high speed serial standards
- Wide dynamic range to observe the true performance of the DUT
- Low noise floor for accurate and repeatable measurements
- Fast measurement speed for real-time analysis
- State-of-the-art calibration techniques reduce measurement errors
- Automatic deskew ensures easy removal of fixture and probe effects
- Full calibration available for the utmost in measurement accuracy
- Quickly obtain accurate TDR/TDT and S-parameter measurements
- Easily locate source of loss, reflections and crosstalk by simultaneous analysis of both time and frequency domain
- Single connection forward and reverse transmission and reflection measurements
- All possible modes of operation (single-ended, differential and mode conversion)
- Measure just the device by utilizing advanced calibration techniques to remove cable, fixtures and probe effects
- Gain insight into high speed interconnect performance through simulated eye diagram analysis and manual scale of eye diagram
- Apply industry standard (PRBS, K28.5) or used specified patterns using the virtual bit pattern generator
- Pre-defined masks for many high speed serial standards
- No need for pulse generators as the eye diagram is synthesized from measurement results
- Hot TDR measurement which allows TDR measurement to be performed while the device is powered ON
Limitations

TDR is not supported in the following configurations:

- If LFE (Low Frequency Extension) is ON, launching TDR will force LFE mode OFF.
- Millimeter Wave configurations do not support TDR either remotely or from the GUI even if TDR is licensed.
- Multiport mode does not support TDR either remotely or from the GUI even if TDR is licensed.

TDR/TDT Measurement

To better understand how to use the TDR option, this section describes the basic TDR/TDT measurement procedure using the VNA.

Operation procedure

1. Connect cables to all test ports.
2. Click the **Setup** tab.
3. Click the **Setup Wizard** (under Basic).
4. Set the measurement condition using the **Setup Wizard**:
   a. Select **Deskew & Loss Compensation** (under **Error Correction**) then click **Next >**.
   b. Click the **Differential 2-Port** button, then click **Next >**.
   c. Click the **Deskew** button, then click **Next >**.
   d. Connect a Thru between Port 1 and Port 3. Click the **Measure** button, and click **Next >**.
   e. Connect a Thru between Port 2 and Port 4. Click the **Measure** button, and click **Next >**.
   f. Connect a Load to Port 1 and click the Port 1 button to measure the Load. Repeat this step for Port 2, Port 3 and Port 4. When finished, click **Apply** to save the measurement.
   g. Click **Next >**.
   h. Connect the DUT to cables. Click the **Measure** button, then click **Next >**.
   h. Set the Rise Time to "35 ps" and select "10-90%" from the **Definition** drop-down list. When finish, click **Apply** to save the settings.
   i. Click the **Finish** button.
5. Click the **Auto Scale** then **All Traces** from the drop-down list.
6. Select Trace 3.
7. Click the **Marker Search** button.
8. Select **Rise Time (10-90%)** from the drop-down list.

**Expected result**

Trace 1 shows the TDR measurement in terms of impedance and Trace 3 shows TDT measurement in terms of voltage. The rise time of Trace 3 will be shown.
Simulated Eye Diagram

This section describes the procedure of simulated eye diagram using the VNA with TDR option.

Operation procedure

1. Connect cables to all test ports.
2. Click the Setup tab.
3. Click the Setup Wizard (under Basic).
4. Set the measurement condition using the Setup Wizard:
   a. Select Deskew & Loss Compensation (under Error Correction) then click Next >.
   b. Click the Differential 2-Port button, then click Next >.
   c. Click the Deskew button, then click Next >.
   d. Connect the DUT to cables. Click the Measure button, then click Next >.
   e. Set the Rise Time to 35 ps and select 10-90% from the Definition drop-down list. When finished, click Apply to save the settings.
   f. Click the Finish button.
5. Click Trace button on the tool bar and select 3 to activate Trace 3.
6. Click Eye/Mask tab.
7. Under Stimulus:
   a. Select PRBS from the Type drop-down list.
   b. Select 2^7-1 bits from the Length drop-down list.
   c. Set the One Lv. (amplitude) to 200 mV.
   d. Set the Data Rate to 1 Gb/s.
8. Click the Draw Eye button under Trigger.

Expected result

The eye diagram (Trace 3) similar to the one shown below is displayed.

- Test Cable and Connector Considerations

Channel and Trace Concepts

It is important for oscilloscope users to note the difference in the concept of channel in oscilloscope and network analyzer.

In network analyzer, channel is referred to the window for displaying traces. Because a channel corresponds to a window, it is called a channel window.

On the other hand, the points on the front panel of the network analyzer where cables and DUTs are connected are called test ports. These test ports are not channels and do not directly associate with channel windows.

The VNA, for example allows you to use up to 150 channels to perform measurements under 150 different stimulus conditions. All traces that are assigned to a channel share the same channel settings.

To learn more about setting the channel and traces, refer to Traces, Channels, Windows, and Sheets.

Enhanced Time Domain Analysis option allows you to use channel 1 only. Up to 16 traces can be displayed in this option (when Differential 2-Port DUT topology and all T or all S traces are selected).

Device Under Test (DUT) Considerations

Maximum DUT Lengths

To convert from DUT length in seconds to distance in free space, multiply the value in time by c, the speed of light in free space. To calculate the actual physical length, multiply this value in free space by Vf, the relative velocity of propagation in the transmission medium. (Most cables have a relative velocity of 0.66 for a polyethylene dielectric or 0.7 for a PTFE dielectric.)

\[ \text{DUT length (m)} = \text{DUT length (s)} \times c \times Vf \]

AC coupled (DC cut) DUTs
Caution is required when measuring AC coupled (DC cut) DUTs.

The response after the capacitor cannot be measured correctly, because the capacitor response overlaps the response from the input and may cause measurement errors.

When measuring AC coupled devices, make sure that the following two conditions are satisfied for proper measurements.

- Capacitance should be equal to or greater than 10 nF
- DUT length should be equal to or less than 6.25 nsec (1.25 meters at $\varepsilon=2.25$)

DUT length is the actual length of the DUT, not DUT Length in the Setup tab in the TDR GUI.

When the above conditions are not satisfied, either:

- Short circuit the capacitor
- Provide open termination at one end of the capacitor and measure from the opposite side.

**Test Cable and Connector Considerations**

Using high quality cables to connect the DUT is recommended in order to minimize measurement degradation. The cables should have low loss, low reflections, and minimum performance variation when flexed.

**Note:** When performing deskew and loss compensation, the same type of cable must be used for all test ports, but they do not necessarily have to be of the same length.

When performing deskew or deskew and loss compensation, use a single connector interface type, such as SMA, or Type-N, for all of the ports to obtain the best results.
Starting andExiting TDR Application

- Starting TDR Application
-Exiting TDR Application

Taking a look at Other topics about Overview

Starting TDR Application

1. On the VNA, press Meas > S-Param > Meas Class....
2. Select TDR, then click OK.
3. In the Confirm Measurement Class Change dialog, click OK to proceed or Cancel to exit.
4. The TDR application is displayed.

Starting TDR application remotely

- SYST:TDR:PRESet launches TDR application without VNA-TDR GUI.

Exiting TDR Application

There are two ways to exit the TDR application.

1. Select a different Measurement Class for the currently active channel.
2. Select the Exit button in the TDR Setup dialog.

Exiting TDR application remotely
- **SYST:PRESet** quits TDR application (VNA-TDR GUI is closed if exists.)
Setting Up the Measurement

- Using Setup Wizard
- Performing Manual Setup
- Performing Error Corrections

Other topics about Enhanced Time Domain Analysis
Setup Wizard guides you to perform the Enhanced Time Domain Analysis measurement setup step-by-step. The wizard appears automatically the first time you execute the Enhanced Time Domain Analysis option. If you check the Show this wizard next start-up option, the setup wizard will appear automatically in the next start-up as well.

Another option to start up the Setup Wizard is from the Setup tab:

1. Click the **Setup** tab.

2. Click the **Setup Wizard** button under **Basic**, as shown below.

3. If you do not want to perform the Enhanced Time Domain Analysis setup by using the wizard, click **Close** to close the **Setup Wizard**.

4. Otherwise, select the type of **Error Correction** among the available options:
   - Deskew
5. If you check the **Show this wizard next start-up** option, the setup wizard will appear automatically in the next start-up.

6. Click **Next >** to start the setup process.

7. Select the topology of the device under test (DUT).

8. Click **Next >**.

9. The next screen of the wizard varies depending on the selection of **Error Correction** option and topology of the DUT.

10. Follow the instructions on the wizard to complete the setup.

**Other topics about Setting Up the Measurement**
Performing Manual Setup

Besides Using the Setup Wizard, you can also perform the Enhanced Time Domain Analysis measurement setup manually. The manual setup is performed at the Setup tab.

- Preset
- Setting DUT Topology
- Setting Stimulus Amplitude Level
- Setting DUT Length
- Performing Error Correction
- More Functions
- Average
- Advanced Waveform
- Hot TDR

Other topics about Setting Up the Measurement

Preset

1. Click **Preset** under **Basic** to preset the VNA.
2. A dialog box appears requesting confirmation. Click **OK** to proceed.
3. All the settings shown in the **Basic** area are changed to default except for the DUT Topology.
4. When you click **Preset**, the calibration and deskew data is deleted. Preset sets all of the settings at default except for the DUT Type.

Setting DUT Topology
1. At the **DUT Topology** under **Basic**, select one of the available options from the drop-down list box. This is the same function as Step 1/4: DUT Topology in the **Setup Wizard**.

2. A dialog box appears requesting confirmation. Click **OK** to proceed.

Selecting the DUT topology executes the preset of the VNA. Therefore, when you change from one DUT topology to another, the calibration and deskew data is deleted.

### Setting Stimulus Amplitude Level

**Note:** Stimulus Amplitude Level is the value for scaling the time domain measurement result.

1. Stimulus Amplitude Level is not related to the actual applied voltage.

2. Click in the text box of **Stim. Ampl.** (Stimulus Amplitude) under **Basic**. An **Entry** dialog box appears. Type the stimulus amplitude level value then click **OK**. The new value is displayed at **Stim. Ampl.** text box.

### Setting DUT Length

The DUT length setting is used to set the time span for time domain measurements. Measurements can be made on longer DUTs, but minimum rise time values may be limited.

**Automatic measurement** - recommended
1. Click **Auto** next to **DUT Length** under **Basic**. The **DUT Length** dialog box of the **Setup Wizard** appears.

2. Click **Measure**.

3. The length of the DUT is measured automatically and used to set the time base.

4. Once complete, a check mark appears beside the **Measure** button.

The automatic measurement feature is available as one of the steps in the **Setup Wizard**.

**Manual entry**

If the length of the DUT is known, the DUT length can be set manually.

1. Enter the DUT length in the **DUT Length** text box under **Basic**.

Any DUT shorter than the DUT length setting can be measured. Therefore, when testing multiple DUTs with different lengths, set the DUT length using the longest DUT to allow for the use of the
same instrument settings for all measurements.

**Performing Error Correction**

There are three error correction options available, as stated below. Refer to Performing Error Correction for more information.

- Deskew
- Deskew and Loss Compensation
- Full Calibration (ECal)

**More Functions**

**Ref. Z**

1. At the Ref. Z (Port Reference Impedance) text box in the More Functions tab, left-click once. An Entry dialog box appears. Type the post reference impedance value then click OK. The new value is displayed in the Ref. Z text box.

**Dielectric Const. and Velocity Factor**

Velocity Factor = 1 / sqrt(Dielectric Constant).

As such, when you change either one, the value of the other changes automatically.

1. To change the value of the dielectric constant, at the Dielectric Const. text box in the More Functions tab, left-click once. An Entry dialog box appears. Type the Dielectric Constant value then click OK. The new value is displayed in the Dielectric Const. text box.

2. The value of the velocity factor is changed in a similar way at Velocity Factor text box in the More Functions tab.

**Source Power**

The signal source level is changed during HOT TDR measurement to avoid device malfunction:

1. At the Source Power text box in the More Functions tab, left-click once. An Entry dialog box appears. Type the source power value then click OK. The new value is displayed in the Source Power text box.

**Bal Port Config**

This button opens the balanced source setting dialog.
The default port allocation is different between PNA/ENA VNAs and PXI/USB VNAs. In PXI/USB VNAs, the left hand DUT ports are odd and the right hand DUT ports are even.

![Port Allocation Diagram]

**Freq Limits Config**

The Enhanced Time Domain Analysis measurement start and stop frequencies can be specified directly using the **Frequency Limits** dialog. This feature allows the Enhanced Time Domain Analysis measurement frequency range to be set narrower than the hardware's frequency range. For example, when using an ECal with a narrower frequency range than the hardware.

1. Click on the **Freq Limits Config** button. The **Frequency Limits** dialog is displayed.

![Frequency Limits Dialog]

2. Specify the start frequency in the **Start Limit** field.
3. Specify the stop frequency in the **Stop Limit** field.
4. Click the **Restore Defaults** button to set the start/stop limits back to the default values.
5. Clicking the **OK** button will apply changes and close the dialog. This causes a TDR preset.
6. Clicking the **Cancel** button will cancel any changes and close the dialog.

**Advanced Mode**

Refer to Advanced Mode.

**Average**
The averaging function allows you to reduce the trace noise. It executes the sweep the number of times specified by the averaging factor when the sweep averaging function is turned ON. To activate the averaging option, go to Average.

1. To turn ON the averaging factor, select the **Averaging** check box in the **Average** tab.

2. Type the averaging factor (number of times the sweep needs to be executed).

3. To turn ON the averaging trigger, select the **Average Trigger** check box.

4. At the **IF Bandwidth** text box, left-click once. An **Entry** dialog box appears. Type the IF bandwidth value then click **OK**. The new value is displayed in the **IF Bandwidth** text box. Reducing IF bandwidth increases the dynamic range.

**Advanced Waveform**

Refer to Advanced Waveform Analysis.

**Hot TDR**

Refer to HOT TDR measurement.
Performing Error Corrections

- Overview
- Deskew
- Deskew and Loss Compensation
- Full Calibration (ECal)

Other topics about Setting Up Measurement

Overview

There are many different approaches of removing the effects of the test fixture and cables from the measurement. The level of difficulty for each error correction technique is related to the accuracy of each method. As such, TDR gives you the flexibility of selecting the desired error correction.

There are three error correction options available, as stated below:

- Deskew
- Deskew and Loss Compensation
- Full Calibration (ECal)

If you use the Setup Wizard, you will be guided through step-by-step to perform the Enhanced Time Domain Analysis measurement setup. This includes performing the error correction. Optionally, you can perform the error correction manually using the Setup tab.

Note: The TDR indicator at the channel window also shows the TDR deskew and calibration status.

Deskew
Deskew automatically compensates the electrical length of the cables and fixtures. Deskew mathematically extends the calibration reference plane to the DUT, hence removes the delay from the test setup effectively. This error correction technique provides good results if the cable and fixture are very well designed.

As deskew does not compensate the loss of cables in the measurement, cables should be low loss and as reasonably short as possible.

1. Click the **Deskew** button under **Basic**.
2. The **Deskew** dialog box of the Setup Wizard appears.
3. Follow the instructions on the wizard and click the **Deskew** button in the dialog box.
4. Deskew is performed and a check mark appears beside the **Deskew** button.
5. Alternatively, you can deskew one port at a time. To perform this, instead of clicking the **Deskew** button, click the **Options** button in the dialog box.
6. At the **Deskew Options** dialog box, you can click one port at a time to deskew it.
8. Click **Measure All** to perform deskew on all the ports. This action is the same as clicking the **Deskew** button. You must deskew all the active ports.

9. At **Standard Type**, select either **Open** or **Short** deskew.

10. Click **OK** to close the **Deskew Options** dialog box.

11. Once complete, click **Finish** on the dialog box.

**Deskew and Loss Compensation**

Deskew and loss compensation mathematically extends the calibration reference plane to the DUT, hence removes the delay and loss from the test setup effectively. This error correction technique is a good compromise between level of difficulty and accuracy.

The same type of cable must be used for all test ports. However, they do not necessarily have to be of the same length.

1. Click the **Deskew & Loss** button under **Basic**.

2. The **Deskew & Loss Compensation** dialog box of the **Setup Wizard** appears.

3. The Deskew & Loss Compensation is a three-step process.

4. Follow the instructions on the wizard and click the **Deskew** button in the dialog box.
5. Alternatively, you can deskew one port at a time, just as in Deskew. To perform this, instead of clicking the Deskew button, click the Options button in the dialog box.

6. At the Deskew Options dialog box, you can click one port at a time to deskew it.

7. Clicking Measure All performs deskew on all the ports at the same time. This action is the same as clicking the Deskew button. You must deskew all the active ports.

8. At Standard Type, select either Open or Short deskew.

9. Click OK to close the Deskew Options dialog box.

10. At Step 2, connect a thru between the ports as per the instruction on the dialog box then click Measure.

   - Use thru with a short and low loss.

11. At Step 3, connect a load to the ports one by one then click the associate button accordingly. Once complete, click Apply to save the measurement.

12. Click Finish on the dialog box.
**Full Calibration (ECal)**

Full Calibration refers to calibration using the Electronic Calibration (ECal) module. It is a complete solid-state calibration solution, which makes calibration fast and easy.

**ECAL Minimum Frequency Check**

The performance of ECal modules with a start frequency of 10 MHz affects time domain accuracy. The firmware will issue the following warning:

The selected ECal does not have optimum low frequency performance. For higher accuracy, use either the DC version of the ECal, or perform mechanical calibration in Advanced Mode.

Also, some ECal modules have a low maximum power limit (-15 dBm) that would degrade time domain performance. Hence, these ECal modules are not recommended for calibration. In this case, the firmware will issue the following warning:

The selected ECal does not have optimum performance. For higher accuracy, use either the DC version of the N4690 Series ECal, or perform mechanical calibration.

**Note:** These warning messages are TDR mode only.

1. Click the ECal button under Basic.
2. The Full Calibration (ECal) dialog box of the Setup Wizard appears.
3. Follow the instructions on the wizard then click the Calibrate button in the dialog box.
4. Follow the instructions in the dialogs that will guide you through the calibration.

5. Click Next >.

6. Fixture Compensation is an optional process.

7. If you choose to perform fixture compensation, follow the instructions on the wizard then click the **Fixture Comp** button in the dialog box. This automatically compensates the electrical length of the cables and fixtures of all the ports.

8. Alternatively, you can compensate one port at a time. To perform this, instead of clicking the **Fixture Comp** button, click the **Options** button in the dialog.

9. At the **Fixture Compensation** dialog box, you can click one port at a time.

10. Clicking **Measure All** compensates all the ports at the same time. This action is the same as clicking the **Fixture Comp** button. You must compensate all the active ports.

11. At **Standard Type**, select either **Open** or **Short** compensation.

12. Click **OK** to close the **Fixture Compensation** dialog box.
13. Once complete, click **Finish** on the dialog box.
Making Measurements

- Setting up Parameters on Each Trace
- Controlling Trigger
- Using Scale/Zooming
- Using Marker and Marker Search
- Using Data and Memory
- Using Gating
- Using Trace Control
- Hot TDR Measurement

Other topics about Enhanced Time Domain Analysis
Setting Up Parameters on Each Trace

- Selecting Trace
- Changing Displayed Trace
- Selecting Parameters
- Defining the Stimulus
- Peeling
- Smoothing

Other topics about Making Measurement

Selecting Trace

Using Mouse

- Double-click on any area of the graph plot to exit from full view.
- Click on the desired trace to select the trace.

Using Hardkey /SoftTab /Softkey

- Press the Prev or Next hardkey.

Using Softkey in TDR GUI

Click on the Trace button and select the trace number from the list as shown below.

Note: The number of traces is changeable and up to 16 traces can be displayed in this option. 16 traces are displayed when Differential 2-port DUT topology, and all time domain (T) and all S-parameter (S) traces are selected.
Changing Displayed Trace

Changing Displayed Trace

Using Mouse

1. Double-click on the single trace graph window to exit from full view of active trace as shown below.

2. Double-click on the desired trace for full view.
Selecting Parameters

Click on the TDR/TDT tab in order to get to the Parameters tab selection as shown below.

The table below shows the Measurement and Format available under the Parameter setting:

<table>
<thead>
<tr>
<th>Measure</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>S-Parameter</td>
<td>Log Mag</td>
</tr>
<tr>
<td></td>
<td>Linear</td>
</tr>
<tr>
<td></td>
<td>Real</td>
</tr>
<tr>
<td></td>
<td>Imaginary</td>
</tr>
<tr>
<td></td>
<td>Group Delay</td>
</tr>
<tr>
<td></td>
<td>SWR</td>
</tr>
<tr>
<td></td>
<td>Phase</td>
</tr>
<tr>
<td></td>
<td>Expand Phase</td>
</tr>
<tr>
<td></td>
<td>Positive Phase</td>
</tr>
<tr>
<td></td>
<td>Smith (Re/Im)</td>
</tr>
<tr>
<td></td>
<td>Smith (G+jB)</td>
</tr>
<tr>
<td></td>
<td>Polar (Re/Im)</td>
</tr>
<tr>
<td>Time Domain</td>
<td>Impedance</td>
</tr>
<tr>
<td></td>
<td>Volt</td>
</tr>
<tr>
<td></td>
<td>Log Mag</td>
</tr>
<tr>
<td></td>
<td>Linear</td>
</tr>
<tr>
<td></td>
<td>Real</td>
</tr>
</tbody>
</table>
The table in the Parameter area changes as the selection of Measure changes. The changes can be referred as below:

<table>
<thead>
<tr>
<th>Measure</th>
<th>Table Content starts with</th>
</tr>
</thead>
<tbody>
<tr>
<td>S-Parameter</td>
<td>Single-Ended S</td>
</tr>
<tr>
<td></td>
<td>Differential Sc, Sd</td>
</tr>
<tr>
<td>Time Domain</td>
<td>Single-Ended T</td>
</tr>
<tr>
<td></td>
<td>Differential Tc, Td</td>
</tr>
</tbody>
</table>

**Defining the Stimulus**

There are two options to choose from under the Stimulus:

- Lowpass Step
- Lowpass Impulse

Only for the Lowpass Step the selection for Rise Time is active. The two options for Rise Time are:

- 10-90%
- 20-80%

The rise time settings in TDR/TDT mode and Eye/Mask mode are independent.
Peeling

When a device has two or more impedance discontinuities, reflections from the second discontinuity reflects off the first discontinuity. This complex interaction of secondary reflections from the stimulus pulse compromises the measured impedance profile and decreases the measurement performance.

TDR peeling compensates for the complicated interaction between the discontinuities. TDR peeling analysis reflects the signals at the source and de-convolves the time domain reflections to create an impedance profile of the device being tested. This option is available when the measurement parameter is set to time domain reflection and the format is impedance.

Limitation

- TDR peeling does not account for frequency response losses (for example, PC board transmission lines are lossy devices). The sum of the waves that are incident on a node are assumed to be equivalent to those exiting the node.

- TDR peeling assumes a lossless transmission line (resistance of 0). Any actual resistance (which causes loss, even at DC) degrades the accuracy of peeling.

- Initial impedance mismatch is the most accurate; as distance increases from initial impedance mismatch down the transmission line, the impedance accuracy decreases.

- TDR peeling cannot be used on TDT responses, because the lack of reflections invalidates the algorithm.

How to set Peeling

1. Click TDR/TDT tab.
2. Select the Peeling check box in the Parameter tab.

Smoothing

Smoothing is only available when S-Parameter is measured and only applicable to reflection coefficient only (S11, S22, S33, S44).

How to set Smoothing

1. Click TDR/TDT tab.
2. Select the Smoothing check box in the Parameter tab.
Controlling Trigger

Making Single/Continuous measurement

Single measurement

- Click on the **Stop Single** button to enable single measurement.

Continuous measurement

- Click on the **Run** button to enable continuous measurement.

Other topics about Making Measurement
Using Scale/Zooming

- Using Autoscale
- Changing Scale Manually
- Zooming

Other topics about Making Measurement

Using Autoscale

1. Select the trace which you want to change the scale.
2. Click on the Auto Scale button on the tool bar or right-click in the graph plot area.
3. Select the desired scale. Refer to the table below for the details of each selection.

<table>
<thead>
<tr>
<th>Scale</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Scale X</td>
<td>Auto scaling X axis only, on the active trace</td>
</tr>
<tr>
<td>Auto Scale Y</td>
<td>Auto scaling Y axis only, on the active trace</td>
</tr>
<tr>
<td>Auto Scale X &amp; Y</td>
<td>Auto scaling both X &amp; Y axis, on the active trace</td>
</tr>
<tr>
<td>Auto Scale All</td>
<td>Auto scaling both X &amp; Y axis, on all traces</td>
</tr>
</tbody>
</table>

Changing Scale Manually

Changing Horizontal Scale

1. Select the trace which you want to change the scale.
2. Click the **TDR/TDT** tab.

- **Using Virtual knob**
  
a. Click the left knob under **Horizontal**. The center of the knob turns blue.
  
b. Scroll up or down the wheel mouse button to change the scale.

- **Type in Entry box**
  
a. Click in the box below the left knob under **Horizontal**. An **Entry** dialog box appears.
  
b. Type the precise value.

- **Clicking Wave icons**
  
a. Click the wave icons above the left knob under **Horizontal**. Details are as table below:

<table>
<thead>
<tr>
<th>Function Icon</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="wave1.png" alt="Wave Icon" /></td>
<td>Click to increase the scale in a 1-2-5 sequence. The width of the waveform compresses. The default value for basic time units is 1.0 ns/div</td>
</tr>
<tr>
<td><img src="wave2.png" alt="Wave Icon" /></td>
<td>Click to decrease the scale in a 1-2-5 sequence. The width of the waveform expands.</td>
</tr>
</tbody>
</table>

**Reference Position for Horizontal Axis**

The reference point of horizontal axis can be selected from the center line or left edge of the displayed graticule.

Click the icon as shown in table below under Horizontal to change the reference point:

<table>
<thead>
<tr>
<th>Function Icon</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="ref1.png" alt="Reference Icon" /></td>
<td>Reference point of the display graticule to the left edge. The position of left edge is not changed even if you change the scale.</td>
</tr>
<tr>
<td><img src="ref2.png" alt="Reference Icon" /></td>
<td>Reference point of the display graticule to the center. The position of center is not changed even if you change the scale.</td>
</tr>
</tbody>
</table>

**Changing Horizontal position**
1. Select the trace which you want to change the horizontal position.

2. Click the **TDR/TDT** tab.

   • **Using Virtual knob**

     a. Click the right knob under **Horizontal**. The center of the knob turns blue.
     b. Scroll up or down the wheel mouse button to change the position.

   • **Type in Entry box**

     a. Click the box below the right knob under **Horizontal**. An **Entry** dialog box appears.
     b. Type the precise value.

   • **Clicking Arrow icons**

     a. Click the arrow icons above the right knob under **Horizontal**. Details are shown in the table below:

     | Function Icon | Details                                                                 |
     |---------------|-------------------------------------------------------------------------|
     |               | Click to increase the delay from trigger; the waveform moves to the left of the display. |
     |               | Click to decrease the delay from trigger; the waveform moves to the right of the display. |

**Changing Vertical Scale**

1. Select the trace which you want to change the scale.

2. Click the **TDR/TDT** tab.

   • **Using Virtual knob**

     a. Click the left knob under **Vertical**. The center of the knob turns blue.
     b. Scroll up or down the wheel mouse button to change the scale.

   • **Type in Entry box**
a. Click the box below the left knob under **Vertical**. An **Entry** dialog box appears.
b. Type the precise value.

- **Clicking Wave icons**

  a. Click the wave icons above the left knob under **Vertical**. Details are as table below:

<table>
<thead>
<tr>
<th>Function Icon</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Click to increase the scale in a 1-2-5 sequence; the waveform height compress.</td>
</tr>
<tr>
<td></td>
<td>Click to decrease the scale in a 1-2-5 sequence; the waveform height will expand.</td>
</tr>
</tbody>
</table>

**Changing Vertical Position**

1. Select the trace which you want to change the vertical position.
2. Click the **TDR/TDT** tab.

- **Using Virtual knob**

  a. Click the right knob under **Vertical**. The center of the knob turns blue.
b. Scroll up or down the wheel mouse button to change the position.

- **Type in Entry box**

  a. Click the box below the right knob under **Vertical**. An **Entry** dialog box appears.
b. Type the precise value.

- **Clicking the Arrow icons**

  a. Click the arrow icons above the right knob under **Vertical**. Details are as table below:
<table>
<thead>
<tr>
<th>Function Icon</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>▼</td>
<td>Click to increase the offset value; the waveform shift downward.</td>
</tr>
<tr>
<td>▲</td>
<td>Click to decrease the offset value; the waveform shift upward.</td>
</tr>
</tbody>
</table>

- Drag and drop

1. Click and hold the y-axis of the graph plot.
2. Drag up or down to the desired position and release the button.

**Zooming**

To zoom in the graph plot:

1. Left-click and hold the mouse button.
2. Drag the area you would like zoom and release the mouse button.
3. Select zoom as shown below.
Using Marker and Marker Search

- Activating Marker
- Moving Marker
- Using Reference Marker
- Searching Max/Min Points on Trace
- Measuring Rise Time
- Measuring Delta Time

Other topics about Making Measurement

Activating Marker

1. Click on the **Marker Off** button.

2. Select 1 from the list to activate Marker 1.

3. The marker button shows Marker Off when there is no active markers. The marker button shows Marker Ref when reference marker is active. This applies to all markers. Active marker has an arrow head pointing down. Inactive markers have an arrow head pointing up. Only markers 1 and 2 have vertical dotted lines. All marker values are displayed at the upper right corner of the graph view. There are a maximum of 9 markers that can be activated.
Moving Marker

- Click and hold on the marker, drag the marker to the desired point and release the mouse button.

Using Reference Marker

When reference marker is used, all 9 markers use reference marker as reference point.

1. Click on the Marker Off button.
2. Select Ref from the list.

Moving reference marker is similar to moving marker. Simply choose the reference marker instead of the marker number.

Searching Max/Min Points on Trace

Searching Max point on trace

1. Click on the desire trace.
2. Click on the Marker Search button.
3. Select **Max** from the list.

**Searching Min point on trace**

1. Click on the desire trace.
2. Click on the **Marker Search** button.
3. Select **Min** from the pull down menu.
4. The marker is constantly on tracking mode when **Max** or **Min** is selected. Even moving the marker with the mouse, the marker tracks the **Max** or **Min** of the trace and points to it.

**Measuring Rise Time**

1. Click on the desire trace.
2. Click on the **Marker Search** button.
3. Select **Rise Time (10-90%)** or **Rise Time (20-80%)** from the list.

The data is displayed at the top right corner of the graph plot.

*Rise Time: 151.48 ps (45.413 mm)*

**Measuring Delta Time**

Delta Time measurement available for Time Domain. Traces other than time domain are not able to use for delta time measurement. Delta time is compared with trace save in memory, if available, else it is compared with the trace selected.

1. Click on the trace that is the starting point for the Delta Time.
2. Click on the **Marker Search** button.
3. Select **Δ Time** from the list and select the **Δ Time** checkbox.
4. Select the trace that will be the stopping point.
5. The trace of the starting point can not be changed, therefore it is selected at the beginning. You can compare Data with Memory, by selecting the same trace. (only if **Data & Memory** is selected using the **Data Mem** button)

5. Select the Position to be measured.
6. Click on the OK button.

The data is displayed at the top right corner of the graph plot.

*Delta Time (Tr7): 624.08 fs (187.09 μm)*
Using Data and Memory

- Storing Data Traces to Memory
- Display the Memory Traces

Other topics about Making Measurement

Data displayed on the graph plot can be stored in the memory and recalled for later use. Data traces stored in the memory will be deleted once TDR option restarts.

Storing Data Traces to Memory

1. Click on the **Data Mem** button.
2. Select **Data -> Mem** from the list.

Display the Memory Traces

1. Click on the **Data Mem** button.
2. Select **Memory** from the list.

Table below explains other functions in the Data Mem list:
<table>
<thead>
<tr>
<th>Function</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data -&gt; Mem</td>
<td>Save Data traces to Memory</td>
</tr>
<tr>

Using Gating

- Overview
- Coupling Gate on Several Traces
- Setting Start/Stop Points
- Selecting Gating Type
- Activating Gate

Other topics about Making Measurement

Overview

Gating provides the ability to observe the effect of a particular circuit element on frequency domain response by virtually removing undesired responses. When you define a gate on time domain plot, the gated section is removed and replaced mathematically with an ideal transmission line having the same electrical delay as the removed section. Gating is applied to time plots of individual parameters. While gating the time domain plot of a parameter, you can observe the effect that gating has on the frequency domain of the same parameter by coupling the relevant traces using the gate coupling feature. By observing the original frequency domain response and the transformed frequency domain response, the effect of the gating operation on the S-parameter data can be seen.

When a discontinuity in a test device reflects energy, that energy will not reach subsequent discontinuities. This can "MASK", or hide, the true response which would have occurred if the previous discontinuity were not present. The Gating feature does NOT compensate for this.

Coupling Gate on Several Traces

Gate Coupling allows two or more traces to share the same gating values. The gating value of the active trace is coupled to other trace(s).

It is used to observe the gated frequency response while setting a gate on time response.

Operational procedure

1. Click the TDR/TDT tab.
2. Under TDR/TDT, click the Gating tab.

3. Under Gating, click the Gate Coupling button.

4. The Gate Coupling dialog box appears.

5. Select the time domain trace and the associated S-Parameter trace. For example, trace of T11 and trace of S11.

6. Click OK.

The gate coupling should not be applied to unrelated responses. For example, TDR (T11) and Insertion Loss (S21).

Selecting a lot of traces the gate coupling makes the response of virtual knobs slow. Type your desired value instead of rotating virtual knobs to specify the value.

Setting Start/Stop Points

Gating is set on the active trace. There are several methods to set the start and stop points of the gate:

Setting points at gating tab
1. Click the **TDR/TDT** tab.

2. Under **TDR/TDT**, click the **Gating** tab.

3. Click on the **Start** or **Stop** virtual knob.

4. The knob is highlighted in blue once its enabled.

5. Click on the virtual several times clockwise to increase the value and anti-clockwise to decrease the value.

6. You can observe the start or stop time in the text box below the virtual knob and gate markers on the active trace.

7. Optionally, you can click the text box under the **Start** or **Stop** virtual knob.

8. An **Entry** dialog box appears.
9. Type the start or stop time and click OK.

10. The new value will be displayed at text box and x-axis of the active trace.

The **Start** virtual knob and text box sets the start time and the **Stop** sets the stop time.

The start time and stop time should be set at a point on which the impedance is close to the reference impedance.

**Setting points at active trace graph plot**

1. On the time domain active trace, drag your mouse across the area to set the gating.

2. Select **Set Gating Range**.

3. You can observe two dashed lines indicating the gate on the graph plot. These are gate markers.

4. You can also observe the time value in the text box below the virtual knob under the **Gating** tab in the **TDR/TDT** area.
Selecting Gating Type

The Enhanced Time Domain Analysis module allows you to choose from the following two gate types:

<table>
<thead>
<tr>
<th>Gate type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Band pass</td>
<td>Removes response outside the gate range</td>
</tr>
<tr>
<td>Notch</td>
<td>Removes response inside the gate range</td>
</tr>
</tbody>
</table>

Operational procedure

1. Click the TDR/TDT tab.
2. Under TDR/TDT, click the Gating tab.
3. Under Gating, select one of the gating types from the Type area.

Activating Gate

Ensure that you have set the start and stop time. Then follow the following procedure:

1. Click the TDR/TDT tab.
2. Under TDR/TDT, click the Gating tab.
3. Under Gating, select the Gating check box.

Switch Gating State

1. Right-click on the time domain active trace.
2. Select Switch Gating State.
3. If gating was turned ON earlier, this step will turn it OFF and vise versa. You can observe the changes in the Gating check box.
Changing Trace Allocation

Changing the trace allocation affects the data display on the graph plot. Table below shows the details of each selection:

<table>
<thead>
<tr>
<th>Allocation</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed</td>
<td>Display mixed of commonly measured time domain and S-parameter data</td>
</tr>
<tr>
<td>All T</td>
<td>Display all Time Domain data for selected device topology</td>
</tr>
<tr>
<td>All S</td>
<td>Display all S-Parameter data for selected device topology</td>
</tr>
</tbody>
</table>

1. Click the **TDR/TDT** tab.
2. Click on the desired trace allocation in the **Trace Control** tab under **Allocation**.

Coupling Marker/Time

1. Click the **TDR/TDT** tab.
2. Click on the desired check box in **Trace Control** tab under **Coupling**.

- Selecting **Marker** under **Coupling** enables all the marker on other traces to be moved in same alignment.
- Selecting **Time** under **Coupling** enables all other traces using the same X axis (Time).
- Selecting **Rise Time** under **Coupling** enables all other traces using the same rise time.
- Selecting **Scale** under **Coupling** enables all other traces using the same scale.

**Target Annotation/Readout**

- Selecting **Trace Annotation** under **Active Trace Only** enables the trace annotation only on an active trace.
- Selecting **Marker Readout** under **Active Trace Only** enables the marker readout only on an active trace.

**Copying Trace Setting**

1. Click on the **Trace Settings Copy** button. The **Trace Settings Copy** dialog box appears.
2. Select the source trace in the **From** list. Select the desired destination trace in the **To** list.
3. Click on the **>> Copy >>** button.

**Copied Parameter**

The following parameters for the following functions are copied by the Trace Settings Copy.

Hot TDR Measurement

- Overview
- Checking Device Malfunction
- Reducing Measurement Error

Other topics about Making Measurement

Overview

Hot TDR refers to TDR measurement while the device is powered ON. During measurement, the measurement signal is applied from the VNA to the transmitter. However, this may cause device malfunction. In addition, the transmitter signal from the DUT device into the VNA ports may cause measurement error. When you measure Hot TDR, the transmitter should be connected with Port 1 for Single END, Port1/2 for differential.

Checking Device Malfunction

The following procedure checks if the Signal Source level from the VNA does not affect the device operation:

1. Measure the reflection on the VNA.
2. Save the results in memory trace.
3. Reduce the signal source level of the VNA at Source Power.
4. Check for significant change on the trace. If the change is significant, reduce the signal source level further to avoid device malfunction.

Reducing Measurement Error
The following procedure reduces the measurement error produced by the device signal.

**Case 1 (For Periodic Bit Pattern)**

If the output signal from device is periodic, set the data rate and execute "Avoid Spurious". This will reduce error due to spurious:

1. Click **Setup** tab and select the **Hot TDR** tab.

2. At the **Data Rate** text box, left-click once. An **Entry** dialog box appears. Type the data rate value and click **OK**. The new value is displayed in the **Data Rate** text box. The Data Rate accuracy should be within ±0.5%.

3. Click the **Avoid Spurious** button to execute the option. The VNA searches for spurious and changes the stimulus setting to avoid the spurious. If the Avoid Spurious is successfully executed, a check mark appears next to the **Avoid Spurious** button. At this point, measurement mode is changed from TDR/TDT to Hot TDR Mode and this is indicated at the channel window as "TDR ?". The blue **SVC** indicator is also turned ON.
   
   a. Eye/Mask option tab is disabled in HOT TDR mode.
   
   b. To reset the HOT TDR mode, simply execute preset or change the DUT topology.

**Case 2 (For Random Data)**

If the output signal from device is random, increase averaging to reduce the measurement error.

**About Avoid Spurious**

If Avoid Spurious fails, the "Spurious Not Found" warning message is displayed. Check mark next to the Avoid Spurious button will not be displayed.

When the following parameter is changed, Avoid Spurious option should be executed again:

- Data Rate
- DUT Length
- Deskew

The setting of Avoid Spurious cannot be stored. To recall the condition of Avoid Spurious, you must execute the Avoid Spurious again after recalling the status setting.

At the execution of Avoid Spurious:

- If the IF bandwidth is over 10 kHz, the IF bandwidth value will be set at 10 kHz.
- If the source power is over -20 dBm, the source power will be set at -20 dBm.

- Showing Eye Diagram
- Displaying Results
- Scaling the Eye Diagram
- Injecting Jitter

Other topics about Eye Diagram and Mask Test

Overview

In the oscilloscope, an eye diagram is often used to analyze signal quality. You can diagnose problems, such as attenuation, noise, jitter, and dispersion that arise or characterize specific parts of the system with one display.

The VNA option TDR provides simulated eye diagram analysis capability, eliminating the need for a hardware pulse pattern generator. The virtual bit pattern generator is used to define a virtual bit pattern. The defined bit pattern is then convolved with the device impulse response to create an extremely accurate measurement based eye diagram.

Showing Eye Diagram

1. Select the trace number which you want to observe the eye diagram.
2. Click the Eye/Mask tab.
3. Click Draw Eye to display the eye diagram.
4. Whenever you change the setting of data pattern, it is required to click Draw Eye to reflect the setting on the waveform.

Displaying Results

1. Select Rise Time Def in the Results tab.
2. Click Draw Eye to display the result.
   Whenever you change the setting of Rise Time Def, it is required to click Draw Eye to reflect on the result.
The following results are displayed on the table under Results.

<table>
<thead>
<tr>
<th>Name</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rise Time</td>

</tbody>
</table>
Height Voltage

Width Second Bit Period - 2 × 3 × Jitter RMS

- Bit Period = 1/Bit Rate
- Input Amplitude = Setting of Level One - Setting of Level Zero
- $T_{\text{rise middle}}$ = The time at which the rising edge cross the middle threshold (50%)
- $T_{\text{fall middle}}$ = The time at which the falling edge cross the middle threshold (50%)

**Overlaying the results on the waveform**

1. Select the Overlay check box in the Results tab.
2. The following results are displayed on the screen.
   - Jitter p-p, Level Zero, Level One, Amplitude, Height (V), Width

**Saving Results into File**

You can save the results as a text file.

1. Click Export button in the Results tab. The Save Eye Result dialog box is displayed.
2. Type your desired file name, then click Save.

**Scaling The Eye Diagram**

By default, the eye diagram is set to Auto Scale. You can also set the scale manually.

1. Click on the **Scale/Mask** tab.

2. Select the **Manual** radio button. This will activate the **Scale / Div** and **Offset** options.
3. Click in the **Scale / Div** text box and input the Y axis scale value.

4. Click in the **Offset** text box and input the Y axis offset value.

**Mask Pattern**

See *Using Mask Test* for more information.

**Injecting Jitter**

See *Using Jitter Injection* for more information.
Selecting Bit Pattern

- Overview
- Bit Pattern Type
- Settings Parameters of Bit Stream

Other topics about Eye Diagram and Mask Test

Overview

TDR can provide simulated eye diagram analysis capability, eliminating the need for a hardware pulse pattern generator. The virtual bit pattern can be selected from:

- Pseudo-Random Bit Sequence
- K 28.5
- User Custom
- Statistical

Bit Pattern Type

The following Bit Patterns can be used to develop an Eye Diagram:
Bit Pattern | Description
--- | ---
PRBS | Pseudo-Random Bit Sequence. An industry standard created from a specified pattern length. For example, when $2^7$ is selected, 127 $(2^7 - 1)$ unique data 'words' are assembled according to the industry standard.
K 28.5 | Industry standard developed by IBM which includes comma (control) characters. The pattern is "00111110101100000101" (20 bits).
User | Bit Patterns that you have created.
Statistical | Bit Patterns produced via statistical calculations of jitter specification. When this option is selected, eye diagram is displayed as "Statistical" type. When Jitter Injection is turned ON, this option is set as the default selection. Refer to Using Jitter Injection.

In the user bit pattern, you can set the same bit pattern as the Pseudo-Random Bit Sequence. However you can get much better resolution in result when you use PRBS.

### Selecting Bit Pattern

1. Select the Eye/Mask tab.
2. Select your desired bit pattern at Type under Bit Pattern.
3. If you select the PRBS option, length is activated. Then, select length under Bit Pattern.

### Using a User Bit Pattern

You can easily create user (custom) bit patterns. The length of bit should be from 2 to 32768 ($2^{15}$). The pattern with only either 0 or 1 can not be accepted (ex. 00, 111, 0000).

### Defining/Saving User Bit Pattern

1. Select the Eye/Mask tab.
2. Select User at Type under Bit Pattern, then User Pattern is activated.
3. Click User Pattern, then Bit Pattern Editor is displayed.
4. Type "0" or "1" to create your bit pattern.
5. Click OK, then the Save Bit Pattern dialog box is displayed.
6. Type your desired file name, then click Save.
7. Saving pattern to the file must be required when you use the user pattern.
Recalling User Bit Pattern

1. Select the **Eye/Mask** tab.

2. Click **User Pattern**, then **Bit Pattern Editor** is displayed.

3. Click **Load**, then **Load Bit Pattern** dialog box is displayed.

4. Select your desired file name, then click **Open**.

5. Click **Ok** to exit **Bit Pattern Editor**.

Settings Parameters of Bit Stream

The following parameter can be set for the bit stream.

<table>
<thead>
<tr>
<th>Label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One Lv.</td>
<td>Eye Diagram Y-axis scaling for bit &quot;1&quot; in volts. Negative voltages are allowed. For Differential Eye Diagrams, these scale values are doubled.</td>
</tr>
<tr>
<td>Zero Lv.</td>
<td>Eye Diagram Y-axis scaling for bit &quot;0&quot; in volts. Negative voltages are allowed. For Differential Eye Diagrams, these scale values are doubled.</td>
</tr>
<tr>
<td>Data Rate</td>
<td>The speed in bits/second which data is transferred over a circuit or a communications line.</td>
</tr>
<tr>
<td>Rise Time</td>
<td>The time that it takes a signal to transition from a low to a high condition. Maximum value is 40% of Bit width (Bit width =1/Bit Rate). The time can be defined by either &quot;10-90%&quot; or &quot;20-80%&quot;. The rise time settings in EYE/MASK mode and TDR/TDT mode are independent.</td>
</tr>
</tbody>
</table>

Defining the parameters

1. Select the **Eye/Mask** tab.

2. Click the text box of desired parameter under **Stimulus**, then the **Entry** dialog box is displayed.

3. Type your desired number by clicking numeric keys on the **Entry** dialog box.
Using Mask Test

- Overview
- Defining Mask
- Executing Mask Test

Other topics about Eye Diagram and Mask Test

Overview

The mask test allows you to verify that a displayed waveform complies with industry-standards definitions for electrical waveforms. To comply with the industry standard, the input waveform must remain outside the shaded mask regions. The mask testing is available in Scale/Mask under the Eye/Mask tab. The TDR uses the same format as Infiniium DCA (86100C), therefore, you can use the MASK file (.msk) stored by DCA (86100C).

The some masks with industry-standards definitions are available in the VNA directories.

Defining Mask

Opening Mask File
<table>
<thead>
<tr>
<th>Items</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>Shows the file name and location which is currently selected. The pre-defined files and templates files are available under C:\Program Files (x86)\Keysight\Network Analyzer\masks.</td>
</tr>
<tr>
<td>Type</td>
<td>Shows the Mask File Identifier. In case of Infiniium DCA, this identifier should be &quot;MASK_FILE_861XX&quot;. However, the VNA does not care about the identifier. The VNA will accept it even if this is other than &quot;MASK_FILE_861XX&quot;. As the pre-installed MASK files are compatible with Infiniium DCA, &quot;MASK_FILE_861XX&quot; is displayed when you use pre-installed MASK files. It is not possible to change this in the Mask Pattern Dialog box.</td>
</tr>
<tr>
<td>Description</td>
<td>Shows the description of MASK file. You can change this in the Mask Pattern Dialog box.</td>
</tr>
</tbody>
</table>

**Loading Mask File**

1. Select the **Eye/Mask** tab.

2. Click the **Mask Pattern** button in the **Scale/Mask** tab, then the **Mask Pattern** dialog is displayed.

3. Select the **File** tab.
4. Click **Load**, then the **Load Mask Pattern** dialog is displayed.

5. Select your desired mask file, then click **Open**.
   
   - If the message prompting you to include absolute values for zero/one level is displayed, define the values of the logic 1 and logic 0 levels in the **Logic 1 Lv (V)** and **Logic 0 Lv (V)** in the **Scale** tab then save the file.

6. Click **Close** to exit the **Mask Pattern** dialog box.

The pre-defined files are read-only file. As you cannot overwrite on them, save the file by clicking **Save As**.

**Scaling Mask**
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Margin (%)</td>

</tr>
</tbody>
</table>

**Changing Margin, Position, Delta T and Logic 0/1 Lv**

1. Load the Mask Pattern.
2. Select the Scale tab.
3. Change the margin number using slider, or typing number.
4. Click the box at your desired parameter of position, delta T and logic 0/1 level.
5. Type the number you want to set.
6. Click **Update** to apply the entered number.
7. Click **Close > Yes** to save the modified scale.

**Set Value at Default**

Click **Default Scale** to set the parameter at default.

**Editing Mask**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>The currently selected region number. The region number defines a mask violation area (or polygon).</td>
</tr>
<tr>

<td>The X and Y positions when Margin in Scale Tab is selected at 100%. This shows the positions of MARGIN_MAX in the .msk file.</td>
</tr>
<tr>
<td>Min.X and Min.Y</td>
<td>The X and Y positions when Margin in Scale Tab is selected at -100%. This shows the positions of MARGIN_MIN in the .msk file.</td>
</tr>
</tbody>
</table>

1. **Load the Mask Pattern.**

2. **Select the Edit tab.**

3. **Move the position of points by either way.**
Using Mouse

a. Click the desired point on the figure of mask, then the point is selected (the point color becomes red).
b. Move the point with drag and drop on the mouse to your desired position.

Entering Position

a. Click desired point on the figure of mask, then the point is selected.
b. Click entry box of X(s) under position, then type number for X axis.
c. Click entry box of Y(V) under position, then type number for Y axis.
d. Click Update to apply the entered number on the selected point.

4. Click Close > Yes to save the modified pattern.

Executing Mask Test

1. Select the Mask Test check box in the Scale/Mask tab.
2. Click Draw Eye to redraw eye pattern and mask.
3. The mask and pass/fail result is displayed on the screen
Available Masks

The following tables list the available standard masks files that you can use. The TDR uses the same format as the Infinium DCA (86100C). The following available masks are the same as ones stored in DCA and stored under C:\Program Files (x86)\Keysight\Network Analyzer\masks.

- SDH/SONET
- Fibre Channel
- Ethernet
- Infiniband
- Serial ATA
- XAUI
- Electrical
- G_984_2

Storing Data and Setting

- Saving/Recalling Setting
- Saving Data
- Saving Touchstone Data
- Saving Displayed Image

Other topics about Enhanced Time Domain Analysis
## Saving/Recalling Setting

- Saving Setting
- Recalling Setting
- Compatibility of State Files

### Saving Setting

The setting of TDR can be saved and recalled. The state file of TDR measurements has .tdr file extension.

1. Setup your configuration which you want to save.
2. Click **File** in the tool bar.
3. Select **Save State** from menu, then the **Save State As** dialog is displayed.
4. Type desired file name.
5. Click **Save**.

When you use 2-channel measurement in the **Advanced Mode**, the channel 2 setting is also saved in the .tdr file.

### Recalling Setting

1. Click **File** in the tool bar.
2. Select **Recall State** from menu, then the **Recall State As** dialog is displayed.
3. Select the file name of state file whose file extension is .tdr.
4. Click **Open**.

### Compatibility of State Files
# Compatibility between Mode

The following table shows the compatibility of state file between mode.

<table>
<thead>
<tr>
<th>Mode</th>

<tr>
<td>Basic</td>
<td>Y</td>
</tr>
<tr>
<td>Advanced</td>
<td>N</td>
</tr>
</tbody>
</table>

Y: Recall is possible.

N: Recall is not possible.
**Saving Data**

The trace data can be saved in `.csv` format.

1. Select the trace which you want to get the data.

2. Click **File** in the tool bar.

3. Select **Save Active Trace Data** or **Save All Trace Data** from menu, then the **Save Trace As** dialog is displayed.

4. Type desired file name.

5. Click **Save**.

**Example of File**

```
# Channel 1
# Trace 4
 Frequency  Formatted Data  Formatted Data
8.49E+06  -5.84E-02  0.00E+00
1.70E+07  -8.27E-02  0.00E+00
2.55E+07  -1.04E-01  0.00E+00
3.40E+07  -1.32E-01  0.00E+00
4.25E+07  -1.52E-01  0.00E+00
5.09E+07  -1.84E-01  0.00E+00
5.94E+07  -2.18E-01  0.00E+00
6.79E+07  -2.70E-01  0.00E+00
```

(data is continued until the end)

---

**Other topics about Storing Data and Setting**
Saving Touchstone Data

- File Extension
- Saving Touchstone Data

Other topics about Storing Data and Setting

File Extension (SnP Format)

The SnP file format is changed depending on the selected DUT topology.

<table>
<thead>
<tr>
<th>File Extension</th>
<th>DUT Topology</th>
</tr>
</thead>
<tbody>
<tr>
<td>.s1p</td>
<td>Single Ended 1</td>
</tr>
<tr>
<td>.s2p</td>
<td>Single Ended 2, Differential 1</td>
</tr>
<tr>
<td>.s4p</td>
<td>Single Ended 4, Differential 2</td>
</tr>
</tbody>
</table>

See the Saving data in Touchstone format for touch stone format.

Saving Touchstone Data

The trace data can be saved in touch stone format.

1. Click File in the tool bar.
2. Select Save Touchstone from menu, then the Save Touchstone As dialog is displayed.
3. Type desired file name.
4. Click Save.
Saving Displayed Image

- Saving Image
- Inverting Display Color

Other topics about Storing Data and Setting

Saving Image

The screen image can be saved in bit map or png format.

1. Click File in the tool bar.
2. Select Save Image from menu, then the Save Image As dialog is displayed.
3. Select the file type in Save as Type from either .bmp or .png.
4. Type desired file name.
5. Click Save.

Inverting Display Color

Inverting display color changes the background color of the screen from black to white. When you print out the saved image on a white paper, the background in white color saves a printer ink.

1. Click File in the tool bar.
2. Select Invert Color from menu, then the background color of the screen is changed from black and white.
3. Save the screen by following the procedure of Saving Image.
Advanced Waveform Analysis

- Overview
- Using Jitter Injection
- Using Emphasis
- Using De-embedding
- Using Equalization

Other topics about Enhanced Time Domain Analysis
In Advanced Waveform Analysis, emphasis and equalization helps to improve the quality of the waveform and subsequently the quality of the eye diagram.

There are two options to display the advance waveform window:

- Click on the **Adv Waveform** tab under the **Setup** tab and click one of these buttons: **Emphasis**, **De-embedding**, **Equalization**.

- Click on **Advanced Waveform** button under the **Eye/Mask** tab

View radio button allows you to select the observation point for TDR/TDT or Eye, according to your
selection. Changing View also affects the trigger mode:

- View before the DUT shows the Stimulus View. At this view, trigger mode at the toolbar changes to "STOP".
- View after the DUT shows the Response View. At this view, trigger mode changes to "RUN".
  - When Stimulus View is selected and the trigger mode "RUN/Single" is selected, the view changes to Response View.

**Other topics about Advanced Waveform Analysis**
Using Jitter Injection

To execute jitter injection, click on Jitter button and check Enable.

When Jitter Injection is turned ON, a check mark appears on the Jitter button. The Stimulus Type (under Eye/Mask tab) is automatically changed to Statistical.

See also Bit Pattern Type.

There are two types of jitter injection available to choose from:

- **Random Jitter** - follows the Gaussian distribution and is represented by the rms value of the Random Jitter distribution.
- **Periodic Jitter** - represented by peak-to-peak value.

In general, Deterministic Jitter and Random Jitter totals up to Total Jitter (TJ). Deterministic Jitter is bounded by a finite magnitude. It can be broken into jitter which is correlated to the data sequence and jitter that occurs independent of data. Periodic Jitter is data independent.
Jitter Unit: You can select from Unit Interval (UI) or Second. Second = Unit Interval / Data Rate

Display Limit: This is a probability density limit. Normally, it is not necessary to change this from default setting. This function allows you to execute a fine tuning of skirt of eye diagram. This applied to eye mask result. So that, you can have the same result on the mask test by adjusting this value. This is not applied to the eye result.
Using Emphasis

1. To execute emphasis, click on Emphasis button and check Enable.

2. Cursor Level:

   - Pre cursor is the ratio between $V_C$ and $V_{b2}$:
     \[
     \text{Pre Cursor} = 20 \log_{10} \left( \frac{V_C}{V_{b2}} \right)
     \]

   - Post 1 cursor is the ratio between $V_{b1}$ and $V_a$:
     \[
     \text{Post 1 Cursor} = 20 \log_{10} \left( \frac{V_{b1}}{V_a} \right)
     \]

   - Post 2 cursor is the ratio between $V_{b2}$ and $V_{b1}$:
     \[
     \text{Post 2 Cursor} = 20 \log_{10} \left( \frac{V_{b2}}{V_{b1}} \right)
     \]

When the emphasis is turned on, the DUT length should be larger than $(1/\text{Data Rate}) \times 3$. 

Other topics about Advanced Waveform Analysis
Using De-embedding

1. To execute de-embedding, click on **De-embedding** button and check **Enable**.
2. If differential topology is selected, load S4P or S2P file. For single ended topology, load S2P file.
3. You can enable each SnP file by checking **Enable** in **Select De-embedding** file.
4. The port orientation is shown and it defers depending on the DUT topology.

**Other topics about Advanced Waveform Analysis**
Using Equalization

To execute equalization, click on **Equalization** button and check **Enable**.

You can either select to use the equation by specifying the variables or equation file.

You must specify four variables in this equation in order to generate the filter. These variables are:

- DC Gain
- Zero Frequency
- Pole 1
- Pole 2

Example of Equalization File

!Keysight Technologies

!VNA-TDR Equalization File

```
# Hz dB
1000000000,-1.53E+01,-3.27E-01  
2000000000,-1.52E+01,-7.34E+01  
3000000000,-1.03E+01,-8.63E+01  
40000000000,-9.88E+00,-1.00E+02
```

-------------------------------------
! Comment
#
Hz MA or DB or RI
Freq1, Data1a, Data1b
Freq2, Data2a, Data2b
Freq3, Data3a, Data3b
.
.
Where

MA: Dataxa = Magnitude (Linear), Dataxb = Phase

DB: Dataxa = Magnitude (dB), Dataxb = Phase

RI: Dataxa = Real, Dataxb = Image

- If there is no Dataxb, Dataxb is taken as 0.
- If there is no MA/DB/RI, MA is selected.
- ! (comment) can be place at any lines (Not only top lines but also in the middle).
- If Freq n > Freq (n+1), then the data at freq (n+1) is ignored.
- If frequency span of setting on the VNA is wider than frequency range of data, the extrapolation is applied.

Error Messages

- File Name Error: is the same as VNA error. This message appears when an error exists in the file name and hence a command is not executed correctly.
- Failed To Read Error. This message appears when the file cannot be opened or if the file does not exist. It also occurs when the format of the file is incorrect or the number of data line is less than 2 or more than 10001.
Advanced Mode

Basic | Easy to use | Available | Locked except for Trace Prev, Trace Next, Trace Max and keys in numeric key pad. | Hidden | Not Available | TDR indicator: Blue In Instrument status bar

1 Setting VNA-TDR to Advanced Mode enables VNA functions which are disabled in Basic Mode. It is possible to set up features that will result in unexpected measurement results. Therefore, only advanced users should use Advanced Mode.

The sample measurements are shown in the measurement examples.

**Advanced Mode Considerations**

In the Advanced Mode, you can access all VNA functions. The setting you changed may affect the measurement unexpectedly. The measurement may not be correct if you have such a case. Therefore, the measurement performance is not guaranteed in the Advanced Mode.

It is known that changing the following settings can cause incorrect measurement.
<table>
<thead>
<tr>
<th>Hard key</th>
<th>Do not use</th>

Activating and Deactivating Advanced Mode

- Activating Advanced Mode
- Deactivating Advanced Mode

Other topics about Advanced Mode

Activating Advanced Mode

1. Select the Setup tab.
2. Click Advanced Mode in the More Functions tab, then the Advanced Mode dialog is displayed.
3. When you want to perform a calibration such as TRL calibration in Advanced Mode, select the check box named Use Advanced Calibration Methods in dialog.
   - When you select the check box, the calibration you did in basic mode is cleared.
4. Click Yes to start the Advanced Mode.
5. The following settings are changed.
   - Softkeys are displayed on the right side of screen
   - All hard keys are unlocked.
   - SVC in the instrument status bar turns blue.

Deactivating Advanced Mode (Returning to Basic Mode)

1. Select the Setup tab.
2. Click Basic Mode button in the More Functions tab, then Advanced Mode dialog is displayed.
3. Click Yes to start the Basic Mode.
4. The application is re-started and all settings are reset.
Frequently Used Functions in Advanced Mode

- For Channel 1
- For Channel 2

Other topics about Advanced Mode

This section provides links to standard functions.

For Channel 1

As channel 1 is for VNA-TDR measurements, you can also use some of the standard VNA functions.

- **Cal** (Mechanical, TRL) (Only when Use Advanced Calibration Methods is checked)
- Marker Search
- Limit Test

For Channel 2

As the channel 2 can be used as one channel, you can use all of the standard functions.

- Measurement Parameter
  - Single-ended & Differential
- Format
- Scale
- Display Allocation
- IFBW
- Cal
- Stimulus
- Power
- NOP
- Sweep Type
- Segment Sweep

- Trigger
- Marker Search
- Limit Test
- Port Z conversion
- De-embedding
- Save/Recall
- Save data (csv, snp)
Measurement Examples

- TDR - PCB Impedance Measurement (Advanced Mode Example)
- 2 Channel Measurement Example (Advanced Mode Example)
This measurement example describes how to measure the characteristic impedance of a single-ended transmission line within a defined zone.

Ensure that the VNA-TDR application is in Advanced Mode in order to follow this example.

Before beginning the PCB impedance measurement, we need:

1. Set Measurement Conditions
2. Define Measurement Zone
3. Set Measurement Zone and Measure Characteristic Impedance

Set Measurement Conditions

1. Click Setup > Setup Wizard.
2. Select Deskew then click Next.
3. Select Single Ended 1-Port and click Next.
4. Follow the instructions then click Deskew. When finished, click Next.
5. Follow the instructions then click Measure. When finished, click Next.
Define Measurement Zone

Using VNA-TDR application GUI:

1. Disconnect the DUT.
2. Click Trace > 1 and double-click on the trace.
3. Click TDR/TDT > Parameters > Linear (under Format).
4. Click AutoScale > X & Y to adjust timebase for the entire response of the DUT is visible.
5. Click Marker > 1.

Using **Hardkey/SoftTab/Softkey** (on the right side of the screen):

6. Click Search > Target > Target Value.
7. Type 0.5 target value into the Target Search entry box then click Target Search. These steps locate the instant t1 on the TDR waveform where the open discontinuity occurs.
8. Connect the DUT.

Using VNA-TDR application GUI,

9. Click Marker > 2.

Using **Hardkey/SoftTab/Softkey** (on the right side of the screen),

10. Click Search > Target > Target Value.
11. Type 0.5 target value into the Target Search entry box then click Target Search. These steps locate the instant t2 on the TDR waveform where the open discontinuity occurs.

Calculate the measurement zone using the formulas below.

Compute the round trip propagation time of the transmission line:

\[ Trt = t2 - t1 = 4.96 \text{ ns} - 0 = 4.96 \text{ ns} \] (refer to the figure below)

Determine the initial instant, \( t_i \), of the measurement zone:
\[ ti = t_1 + 30\% Trt = 0 + (0.3) \times 4.96 \text{ ns} = 1.49 \text{ ns} \]

Determine the final instant, \( tf \), of the measurement zone:

\[ tf = t_1 + 70\% Trt = 0 + (0.7) \times 4.96 \text{ ns} = 3.47 \text{ ns} \]

Set Measurement Zone and Measure Characteristic Impedance

1. Click TDR/TDT > Parameters > Impedance (under Format).
2. Click TDR/TDT. Type in \( 25 \) into scale/div (left) entry box under Vertical.
3. Click TDR/TDT. Type in \(-75\) into position (right) entry box under Vertical.

Using Hardkey/SoftTab/Softkey (on the right side of the screen):

4. Click Search > Main > Domain then select User 1.
5. Click Search > Main > Domain Start. Type in 1.49 ns in the entry box.
6. Click Search > Main > Domain Stop. Type in 3.47 ns in the entry box.
7. Click Math > Analysis > Statistics.... The Trace Statistics dialog is displayed.
8. In the **Trace Statistics** dialog, select **User 1** from the drop down menu then click **OK**.

9. Click the left side (small button) of **Math > Analysis > Statistics...** to enable statistics and measure the characteristic impedance.

![Image of network analyzer with trace statistics dialog open]

The characteristic impedance is the mean value, 49.91 U.
2 Channel Measurement Example

- Overview
- Procedure

Other topics about Measurement Examples

Overview

This example shows a 2 channel measurement in the Advanced Mode.

2 channel measurements allow you to make the following measurements:

- TDR measurement on channel 1
- More customized S-parameter measurement on channel 2

**Note:** S-parameter measurements in Channel 1 are used for the time domain transformation. In order to ensure correct time domain results, the S-parameter settings for TDR are not accessible by the user. The optimum settings are calculated within the TDR algorithm. However, there are cases when the user may want specific settings for their S-parameter measurements. For these cases, another channel is used for customization (TDR works for Channel 1 only).

Here is the sequence of this example.

- Setup for channel 1
  1. Deskew
  2. Auto DUT length
  3. Set rise time
  4. Setup limit table for the trace 1

- Setup for channel 2
1. Setup start and stop frequency and IF Bandwidth.
2. Setup Sdd11 of Balance-Balance measurement
3. Setup limit table for the trace 1
4. Full 4-port calibration with ECal

- Measurement for channel 1
  1. Trigger
  2. Auto scale

- Measurement for channel 2
  1. Trigger

**Procedure**

**Preparation for 2 Channel Measurement**

1. Connect E-Cal on the USB port on the front panel.
2. Connect cables to all test ports.
3. Activate Advanced Mode (Do not select the **Use Advanced Calibration Methods** check box)
4. Click the **Stop Single** button to stop the trigger.

Using **Hardkey/SoftTab/Softkey** (on the right side of the screen):

1. Press **Trigger > Main > Trigger...** to access the Trigger dialog.
2. Under **Trigger Scope** select **Active Channel** then click **OK**.
3. Press **System > System Setup > Sound** then adjust the setting to 0 (zero) to turn off the beeper warning.

**Setup for Channel 1**

1. Click the **Setup** tab in the TDR GUI.
2. Click **Setup Wizard** (under **Basic**).

3. Set the measurement condition using the **Setup Wizard**:

   a. Select **Deskew** (under **Error Correction**) then click **Next >**.
   b. Click the **Differential 2-Port** button, then click **Next >**.
   c. Click the **Deskew** button, then click **Next >**.
   d. Click the **Measure** button, then click **Next >**.
   e. Set the **Rise Time** to **45 ps** and select **20-80%** from the **Definition** drop-down list.
   f. Click the **Finish** button.

**Limit Test Setup**

Using **Hardkey/SoftTab/Softkey** (on the right side of the screen):

1. Ensure that Trace 1 is selected.

2. Press **Math > Analysis > Limits...** to access the **Limit Test Setup** dialog.

3. Check **Limit Test ON** to turn on the limit test.

4. Check **Limit Line ON** to turn on the limit line then click **OK**.

5. Click **Math > Analysis > Limit Table** then select **Limit** to display the limit table.

6. Edit the table as shown below.

<table>
<thead>
<tr>
<th>Type</th>
<th>Begin Stimulus</th>
<th>End Stimulus</th>
<th>Begin Response</th>
<th>End Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Max</td>
<td>0 s</td>
<td>1 ns</td>
<td>105 U</td>
<td>105 u</td>
</tr>
<tr>
<td>2 Min</td>
<td>0 s</td>
<td>1 ns</td>
<td>75 U</td>
<td>75 U</td>
</tr>
</tbody>
</table>

**Setup for Channel 2**

1. Click **Trace > Trace Setup > Add Trace** then select **New Trace + Channel + Window**.

2. Click **Trigger > Main > Hold**.

3. Press the **Freq** hardkey. A table is displayed below the window.

   **Note:** When pressing the **Freq** hardkey, the table is shown in Channel 1 since the sweep is set to segment. For channel 2, the default would be linear sweep, so the necessary parameters will need to be set up using the softkeys.
4. Edit the table as shown below.

<table>
<thead>
<tr>
<th></th>
<th>State</th>
<th>Start</th>
<th>Stop</th>
<th>Points</th>
<th>IFBW</th>
<th>Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>On</td>
<td>1 GHz</td>
<td>3 GHz</td>
<td>29</td>
<td>10 kHz</td>
<td>5 dBm</td>
</tr>
</tbody>
</table>

5. Press **Cal > Fixtures > Apply Fixtures ON** to turn on the fixture simulator.

6. Click **Setup > Layout > Measure...** to access the Measure dialog.

7. In the Measure dialog, select the Balanced tab.

8. Check the desired balanced measurement (for example, Sdd21), then click **Apply** to view the measurement result.

9. When finished, click **OK**.

**Full 4-port Calibration**

1. Connect 4 Port Ecal with the cables.

2. Press **Cal > Other Cals > Ecal...**.

3. Follow the wizard for a 4-Port ECal.

**Limit Test Setup**

Using **Hardkey/SoftTab/Softkey** (on the right side of the screen):

1. Press **Math > Analysis > Limits...** to access the Limit Test Setup dialog.

2. Check Limit Test ON to turn on the limit test.

3. Check Limit Line ON to turn on the limit line then click **OK**.

4. Click **Math > Analysis > Limit Table** then select Limit to display the limit table.

5. Edit the table as shown below.

<table>
<thead>
<tr>
<th></th>
<th>Begin Stimulus</th>
<th>End Stimulus</th>
<th>Begin Response</th>
<th>End Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Min</td>
<td>100 MHz</td>
<td>1.25 GHz</td>
<td>-1.5 dB</td>
</tr>
<tr>
<td>2</td>
<td>Min</td>
<td>1.25 GHz</td>
<td>2.5 GHz</td>
<td>-5 dB</td>
</tr>
<tr>
<td>3</td>
<td>Min</td>
<td>2.5 GHz</td>
<td>7.5 GHz</td>
<td>-7.5 dB</td>
</tr>
</tbody>
</table>
Measurement in Channel 1

1. Connect the DUT with the cables.

2. Click the **Stop Single** button in the TDR GUI to make one single measurement.

3. Select Trace 1.

4. Click **Auto Scale** in the TDR GUI, then select **All Traces**.

Measurement in Channel 2

1. Select the S-parameter trace of interest.

2. Click **Trigger > Main > Single** to make one single measurement.
Connecting with PathWave Vector Signal Analysis (89600 VSA)

Connecting to the 89600 VSA software allows for greater signal evaluation and troubleshooting.

Supported Models

- PXI VNA: M9800A to M9808A
- USB VNA: P5000A to P5008A, P5020A to P5028A
- PNA-B VNA

Requirements

- The 89600 VSA Version 2020 Update 0.1 or later is required.
- VNA
  - Firmware Version A.14.10.12 (A.14.60.xx for PNA-B VNA) and above
  - Option 190 Vector signal analysis hardware (PXI/USB VNA only)
  - S95090A/B (PXI VNA) or S97090A/B (USB VNA) or S93090xA/B (PNA-B VNA) Spectrum Analysis software

Limitations

- Negative Trigger Delay is not supported
  - Generally, VSA supports negative delay, in case of connecting with SA or Scope. But, VNA connection case, the negative delay is not supported because VNA trigger system hardware does not support negative delay. This is further follow-on feature.
- 100MHz Reference Input is not supported. (Only 10 MHz Reference Input is supported.)
  - The External Reference Frequency field is always grayed out in the reference source selection under Utilities > Frequency Reference.... 100MHz external input cannot be selected.
- User Cal for SA channel
SA channel is used for the VSA-VNA connection. When establish connection between VSA and VNA, VSA creates hidden SA channel on VNA. Then, VSA queries IQ data from the SA channel on VNA. During the connection, the user should not control the hidden VNA SA channel, otherwise, the VSA-VNA connection might be broken. VNA SA channel has the user cal function, but in the 89600 VSA-VNA connection, user cal on the hidden SA channel is not supported.

Connecting with the 89600 VSA Software

Before connection, make sure that the VSA Software and its license are installed.

VNA Application

1. Launch Network Analyzer application from Windows Start or Shortcut on the desk top.
2. Click \textit{System} > \textit{System Setup} > \textit{Remote Interface}.
3. Check the HiSlip.

IO Connection Expert

1. Execute IO Connection Expert from Windows Start.
2. Click \texttt{+Add}, then select \texttt{LAN instrument}.
3. Add LAN device dialog box is displayed.
4. Select \texttt{Enter Address} Tab.
5. Type your host name in Hostname or IP Address in Set LAN Address
6. Select \texttt{HiSlip} in Set Protocol
7. Type your remote name in Remote Name: (TCPIP0::<hostname>::hislip<address>)
8. Check \texttt{Allow *IDN Query}.
9. Click Test This VISA address, then confirm if your address is verified correctly.
10. Click OK.

**VSA Application**

1. Execute 89600 VSA application from Windows Start.

2. Select **Utilities > Hardware > Discovered Instruments...**

3. Open **SIM** option and make sure that the Vector Network Analyzer entry matching your hardware is displayed in the list. If not, check the VSA version.

4. Click Rediscover icon to find TCPIP0 connection, then the VNA connection will be displayed.

5. Select **Configurations** tab.

6. Click +, then select "Keysight Network Analyzer" and click ">" to register your VNA.
7. Select your VNA in “Current Analyzer Configuration” option. Then, VSA will connect with VNA to start measurements by VNA.
Low Frequency Extension (LFE)

- Overview
- Starting and Exiting LFE
- LFE Calibration
Overview

The 2-port and 4-port Low Frequency Extension (LFE) options add additional hardware to extend the start frequency of the VNA down to 900 Hz.

Note: Source and Receiver frequencies MUST BE EQUAL if both are in the LFE frequency band and LFE is turned on. If they are both in the LFE band and they are not equal, the following error message is displayed and the VNA will go into Hold mode:

In this topic:

Starting and Exiting LFE

In this topic:

- Starting LFE
- Starting LFE with Auto-Enable
- Exiting LFE

Starting LFE

**How to start LFE**

**Using Hardkey/SoftTab/Softkey**

1. Press **Sweep > Source Control > LF Extension**.
2. Ensure that **ON** is selected in the **LF Extension** softkey.

**Using a mouse**

1. Click **Stimulus**
2. Select **Sweep**
3. Select **Source Control**
4. Select **LF Extension [on/OFF]**

Exiting LFE

1. On the VNA, press **Sweep > Source Control > LF Extension**.
2. Ensure that **OFF** is selected in the **LF Extension** softkey.
LFE Calibration

The procedure in this topic describes how to perform a calibration using the Cal All Calibration Wizard method, which allows multiple channel calibration in a single session.

**Note:** Beginning with the A.12.80 release, Cal All has been extended in order to deal with the new Low Frequency Extension option. If a user has a mixture of LFE and non-LFE channels and they would like to use Calibrate All to calibrate them at the same time, two calibration channels are created to account for the hardware differences between the two situations. When using the GUI or COM to set calibration and stimulus conditions, the settings are applied to both calibration channels. With SCPI, the user can query the primary guided calibration channel using `SYST:CAL:ALL:GUID:CHAN:VAL?`. This will return the primary calibration channel. When subsequent Guided Cal commands are used, settings will be transferred to the second calibration channel. If there is a desire to set these settings separately, the user should query for all Cal All Calibration channels with `SYST:CAL:ALL:GUID:CHAN:LIST?`. The user should set values for the primary calibration first, and then secondary calibrations. When initializing the calibration and acquiring steps, use the primary cal all channel number.

For information about other calibration methods that can be used, refer to the following links:

- Basic Cal
- Smart Cal
- Response Cal
- Source Power Cal

**Cal All Procedure**

1. Ensure that the measurement classes to calibrate are active.

2. Press **Sweep > Source Control > LF Extension ON.**

3. Ensure that the measurement frequency range is set properly.

4. Press **Cal > Main > Other Cals > Cal All...** to launch the following dialog showing the active measurement classes:
5. Check the measurement classes to calibrate.

6. Select the ports, then click on the **Apply to all channels** button to apply the port selections to all channels.

7. Click **Next**, then confirm or change the calibration properties in the **Measurement Class Cal Properties** dialog.

8. Click **Next** to access the **Calibration Attenuator Settings** dialog.

9. In the **Calibration Attenuator Settings** dialog, perform the following:

   a. Set the attenuator settings. Learn more.

   b. Click on the **Noise Reduction** button to improve measurement accuracy. Learn more.

   c. Click on the **Mechanical Devices** button to view all switches and attenuators in the VNA. Learn more.

10. Click **Next**, then select the DUT connectors and calibration kits in the **Select DUT Connectors and Cal Kits** dialog.

11. Click **Next** to access the **Power Cal Settings** dialog.
12. In the **Power Cal Settings** dialog, perform the following:

   a. Check **Use Multiple Sensors** if more than one power sensor is needed to cover the frequency range then select a sensor from the **Sensor** down menu.

   b. Learn more about **Accuracy Tolerance** and **Max Number of Readings**.

13. Click **Next** and follow the calibration process until completed.
Overview

The N5290A (900 Hz to 110 GHz) and N5291A (900 Hz to 120 GHz with over range to 125 GHz) are broadband network analyzer systems that utilize compact, broadband remote heads.

The standard system is comprised of the following components:

- N5222B, N5227B, N5242B, or N5247B VNA (see N5290A/N5291A configurations)
- N5292A Test Set
- N5293A (900 Hz to 110 GHz) or N5295A (900 Hz to 120 GHz) Frequency Extenders

In this topic:

- Features
- Capabilities
- N5293A/95A Frequency Extender LED States

See Also

Keysight Double-Ended Torque Wrench for 1.0 mm Connectors (internet connection required)

Features

- Power output of 0 dBm at 110 GHz
- Wide receiver and system dynamic range
- Excellent system stability
- Compact remote heads with 1 mm connectors
- Single module cable for easy setup
- Supports several of the existing VNA/PNA-X software applications at millimeter wave frequencies
- Available in 2-port and 4-port configurations
- All ports configured for use at millimeter wave frequencies
- Measurements down to 900 Hz
- Supports both single sweep Broadband and Banded waveguide measurements

Capabilities

- ONLY the applications listed in the Supported Applications table are supported
- Banded measurements require the N5292A test set
● No automatic power leveling. However, after performing an Installation Calibration, the source power at the output of the N5293A or N5295A Frequency Extender is adjustable.

● No DC power connector in N5292A test set to provide bias voltage to external frequency extenders for banded measurements

● Frequency extender modules cannot be HOT swapped while test set is powered on

● Applications that require the use of source and receiver attenuators DO NOT apply to a millimeter wave system

### N5293A/95A Frequency Extender LED States

The following is a list of possible LED states:

- **Blue**: Connected and addressed by N5292A Test Set
- **Green**: Standby
- **Orange**: Standby or warmup
- **Red**: Error condition
- **Off**: N5293A/95A is turned off

Starting and Exiting Millimeter Wave Mode

In this topic:

- Starting Millimeter Wave Mode
- Exiting Millimeter Wave Mode
- Starting and Exiting Low Frequency Extension (separate topic)

**Note:** The Low Frequency Extension (LFE) is disabled by default. LFE must be enabled to extend the low-end frequency range from 10 MHz down to 900 Hz.

### Starting Millimeter Wave Mode

#### How to start Millimeter Wave Mode

**Using Hardkey/SoftTab/Softkey**

1. Press **Setup > External Hardware > Millimeter Config.**
2. In the **Millimeter Configuration** dialog, select a banded or broadband configuration.
3. Configure the system then click **OK.**

**Using a mouse**

1. Click **Instrument**
2. Select **Setup**
3. Select **External Hardware**
4. Select **Millimeter Config...**
5. In the **Millimeter Configuration** dialog, select a banded or broadband configuration.
6. Configure the system then click **OK.**

### Exiting Millimeter Wave Mode
### How to exit Millimeter Wave Mode

#### Using Hardkey/SoftTab/Softkey

1. Press **Setup** > *External Hardware* > *Millimeter Config*.

2. In the *Millimeter Configuration* dialog, select **Standard PNA**.

3. Click **OK**.

#### Using a mouse

1. Click **Instrument**.

2. Select **Setup**.

3. Select **External Hardware**.

4. Select **Millimeter Config...**.

5. In the *Millimeter Configuration* dialog, select **Standard PNA**.

6. Click **OK**.
Millimeter Configuration

This topic describes the Millimeter Configuration dialog functions used to configure the N5290A/91A for broadband or banded measurements.

In this topic:

- Accessing Millimeter Configuration Dialog
- Broadband Millimeter Configuration Dialog
- Banded Millimeter Configuration Dialog
- Warning Messages

See Also

- N5290A/91A (N5292-90026) Millimeter System Service Guide (requires internet connection)
- Broadband System Measurement Setup
- Banded System Measurement Setup

Accessing Millimeter Configuration Dialog

- Press Setup > External Hardware > Millimeter Config.

Broadband Millimeter Configuration Dialog

<table>
<thead>
<tr>
<th>Programming Commands</th>
<th>Broadband Millimeter Configuration dialog box help</th>
</tr>
</thead>
</table>
Select Configuration  Lists the Standard VNA configuration, N529xA configuration, and other configurations that you have created.

- Click **New** to create a new Millimeter Module configuration. A name is automatically selected. Edit the Selected Configuration field to change the configuration name.

- Click **Remove** to delete the selected Millimeter Module Configuration.

- Select **N5290A Broadband** or **N5291A Broadband**

- For banded, define a frequency band.

- Select **Standard PNA** to exit the Millimeter mode to use the analyzer as a standard VNA.

**Properties**

**Name**  Shows the currently selected configuration. Edit this field to change the configuration name. Type a unique name using only alphanumeric and underscore characters.

**Test Set**  When **N5290A Broadband** or **N5291A Broadband** is the selected configuration, the N5292A test set is automatically selected. No other test set can be selected for the Broadband configuration.

**Enable Modules**  Enable or disable modules (frequency extenders) for the corresponding ports. The check boxes are disabled if a test set is attached and no module is detected on the corresponding port.
**Test Set IF... button**

![Test Set IF Switch settings for Channel N](image)

**Test Set IF Switch settings for Channel N**  Route the Reference or Test IF to the front panel (Front) or rear panel (Normal) of the test set. The Normal setting sets the IF bandwidth to 40 MHz. The Front setting sets the IF bandwidth to 2 GHz. Each port has a Reference IF and a Test IF switch. Each IF switch is independent per port and per channel. At preset, the default is Normal. IF switch settings are saved with the instrument state.

**Installation Cal...**  The installation calibration adjusts the source power at the output of the N5293A or N5295A Frequency Extender. It also adjusts for IF path loss variation. These can change each time a frequency extender is moved from one port to another, or from one system to another. This calibration should be done each time a change is made to the configuration. For a procedure, refer to Installation Cal.

**Frequencies**

**Port**  This is the port number of the VNA when in Standard PNA mode or the port number of the N5292A test set when in N529xA Broadband mode.

**Type**  The port type is set to Module when a frequency extender (N5293A or N5295A) is detected at the port. The Enable Modules checkbox will be checked for the port. When a frequency extender is not detected at the port, or the Enable Modules for the port is deselected, VNA is displayed to specify the standard VNA operation at the port.

**Start/Stop**  Displays the Start and Stop frequency of the frequency extenders (N5293A or N5295A) connected to each port and/or any VNA port in standard mode. Start/stop frequencies can be set by pressing Freq > Main > Start or Stop then entering the frequency.

**Cancel**  Closes dialog box without saving changes.

**OK**  Saves the configuration and the VNA is Preset before making the appropriate settings.

**About MM...**  Displays information about the current hardware configuration.
Banded Millimeter Configuration Dialog

Select Configuration  Lists the Standard VNA configuration and other configurations that you have created.

- Click **New** for first-time use.
- For the N529xA, select **N529xA Broadband**.
- For banded, define a frequency band.
Select **Standard PNA** to exit the Millimeter Configuration dialog.

**Name**  Shows the currently selected configuration. Edit this field to change the configuration name. Type a unique name using only alphanumeric characters and underscore.

**New**  Click to create a new Millimeter configuration. A name is automatically selected. Edit the Name field to change the configuration name.

**Remove**  Deletes a Millimeter Configuration.

**Properties**

**Test Set**  Select a test set to use in the current configuration. The firmware verifies that the selected test set is connected. If the selection does not match the connected test set, an error message is displayed. However, you are not prevented from continuing.

**Enable Modules**  Enable or disable modules (frequency extenders) for the corresponding ports. The check boxes are disabled if a test set is attached and no module is detected on the corresponding port.

**Module IF Gain**  When Auto is selected, the IF gain is automatically adjusted depending on the frequency of operation to avoid overdriving the receivers. In addition, you can manually select 0 dB, 2 dB, 4 dB, 6 dB, 8 dB, 10 dB, 11 dB, 13 dB, or 15 dB.

**Max Power Limit at Module RF IN**  The maximum mmWave module RF input is limited to this value when **Test Set RF ALC** is OFF. When you exit this dialog box using **OK**, set the power out of the VNA using the **Power and Attenuator dialog**.

**Offset**  Sets the loss of the cables. The mmWave module RF input is adjusted by this amount. Positive offset increases the power.

**Slope**  Helps compensate for cable and test fixture power losses at increased frequency. The mmWave module RF input power increases as the sweep frequency increases in dB/GHz. The slope is defined relative to the mmWave module RF input frequency. The slope starts at 0 Hz and a positive slope will increase the power level. Range is +/- 2 dB/GHz.

**Test Set IF...** button
**Test Set IF Switch settings for Channel N**  Route the Reference or Test IF to the front panel (Front) or rear panel (Normal) of the test set. The Normal setting sets the IF bandwidth to 40 MHz. The Front setting sets the IF bandwidth to 2 GHz. Each port has a Reference IF and a Test IF switch. Each IF switch is independent per port and per channel. At preset, the default is Normal. IF switch settings are saved with the instrument state.

Installation Cal... The installation calibration adjusts the source power at the output of the N5293A or N5295A Frequency Extender. It also adjusts for IF path loss variation. These can change each time a frequency extender is moved from one port to another, or from one system to another. This calibration should be done each time a change is made to the configuration. For a procedure, refer to Banded Installation Menu Calibration.

### Frequency Settings

**Multiplier RF IN**  RF Frequency Range (displayed in grey fields) multiplied by the multiplier value equals test port frequency range.

**Multiplier LO IN**  LO Frequency Range (displayed in grey field) multiplied by this value equals the test port frequency. The IF frequency is:

- PNA-X models = 7.438 MHz

**Test Port Frequency**  Set the Start and Stop frequencies of the selected configuration at the test ports. This becomes the displayed Start and Stop frequency of the VNA.

### Important Notes

- To set Test Port Frequency, first set the appropriate **Multiplier** values that are specified in your mmWave module documentation.
- Ensure that the RF and LO Frequencies (highlighted below) are within the frequency range of the sources. The VNA offers no warning if they are NOT.

<table>
<thead>
<tr>

<td>13.7500000000 GHz</td>
</tr>
</tbody>
</table>

### Source

Click a button to launch the **External Devices dialog** where you can select an internal or external source to be used for the VNA LO source or VNA RF source.

**Cancel**  Closes dialog box without saving changes.

**OK**  Saves the configuration and the **VNA is Preset** before making the appropriate settings.
About MM... Displays information about the current hardware configuration.

Warning Messages

The following dialog indicates that an N529xA Broadband configuration is active but some hardware is missing. It will only list the hardware that was not detected. In this case the test set and two selected heads were not found. The **Do not show this dialog again** check will suppress this dialog until the firmware is restarted.

This following dialog indicates that an N529xA Broadband configuration is active but some hardware is uncalibrated. It will only list the hardware that is uncalibrated but a full calibration should be executed if anything has changed. The **Do not show this dialog again** check will suppress this dialog until the firmware is restarted. For a calibration procedure, refer to Installation Cal.
The following millimeter hardware has changed:
- N5292A testset
- Port 1 millimeter head
- Port 2 millimeter head

Please press the button below to perform a millimeter system Installation Cal.

Do not show this dialog again.

Installation Cal... Cancel Help
Calibration

The procedure in this topic describes how to perform a calibration using the **Cal All Calibration Wizard** method, which allows multiple channel calibration in a single session.

Also described here is the **Installation Cal**, which should be done each time a change is made to the configuration, and the **Banded Installation Menu**, which is displayed only when a calibration is out of date or has not been performed.

Calibration procedures accessed in the user interface vary depending on which application (*Measurement Class*) is active. For information about other calibration methods and their purpose, refer to the following links:

- Basic Cal (separate topic)
- Smart Cal (separate topic)
- ECal (separate topic)
- Response Cal (separate topic)
- Source Power Cal (separate topic)
- Mixer Char Wizard (separate topic)
- Phase Reference Wizard (separate topic)
- Cal All Procedure

- Installation Cal
- Creating a Power Table
- Installation Calibration on a Banded Configuration

**Cal All Procedure**

A power table can be used instead of multiple power sensors to cover a wide frequency range. In addition, a power table can be used when the measurement frequency exceeds the frequency range of the power sensor (typically > 110 GHz). Refer to **Creating a Power Table** for information on how to create a power table.

1. Ensure that the measurement classes to calibrate are active.

2. Press **Cal > Main > Other Cals > Cal All...** to launch the following dialog showing the active measurement classes:
5. Check the measurement classes to calibrate.

6. Select the ports, then click on the **Apply to all channels** button to apply the port selections to all channels.

7. Click **Next**, then confirm or change the calibration properties in the **Measurement Class Cal Properties** dialog.

8. Click **Next** to access the **Calibration Attenuator Settings** dialog.

9. In the **Calibration Attenuator Settings** dialog, perform the following:

   a. Set the attenuator settings. **Learn more.**

   b. Click on the **Noise Reduction** button to improve measurement accuracy. **Learn more.**

   c. Click on the **Mechanical Devices** button to view all switches and attenuators in the VNA. **Learn more.**

10. Click **Next**, then select the DUT connectors and calibration kits in the **Select DUT Connectors and Cal Kits** dialog.

11. Click **Next** to access the **Power Cal Settings** dialog.
12. In the **Power Cal Settings** dialog, perform the following:

   a. Check **Use Multiple Sensors** if more than one power sensor is needed to cover the frequency range then select a sensor from the **Sensor** drop down menu.

   b. Otherwise, check **Use Multiple Sensors** then select the power table from the **Sensor** drop down menu. Learn how to create a power table.

   c. Learn more about **Accuracy Tolerance** and **Max Number of Readings**.

13. Click **Next** and follow the calibration process until completed.

**Installation Cal**

This calibration should be done each time a change is made to the configuration.

1. Press **Setup > External Hardware > Millimeter Config**.

2. Click **New** to create a new configuration or select one from the list under **Select Configuration**.
3. If desired, change the name shown in the **Name** field.

4. Click on the **Installation Cal...** button to launch the calibration. The following dialog is displayed.

![Millimeter Installation Cal](image1)

5. Connect a load to the port then click the **Measure** button.

![Millimeter Installation Cal](image2)
6. When finished, the following dialog is displayed. Remove the load then click the **Finish** button.

![Millimeter Installation Cal](image1)

7. The following dialog is displayed until the calibration is finished.

![Millimeter Installation Cal](image2)

**Creating a Power Table**

A power table is a text file with data that describes the output power of the module as a function of frequency. This is valid when the frequency extender module is driven at high levels (+11 dBm). This file may have been created for you by a third party or shipped with your frequency extender Module. If not, you can create this *.prn file from the manufacturer's specification for the frequency extender module.

This file can be created manually, using a text file program such as Notepad.

1. Copy the header information, and create the file with two columns, one for frequency and one for output power.
1.

Example .prn file

2. Name the power table file **pawertable1.prn**, where "1" corresponds to the port number. This file must be stored in the following directory on the VNA:

   C:\ProgramData\Keysight\Network Analyzer\Configurations\<configuration name>\n
   where *configuration name* is a directory name that is also the name of the currently selected configuration in the **Millimeter Configuration** dialog. For example, "N5291A Broadband".

3. Once the power table has been created and saved to the directory shown above, it will be listed in the **Sensor** drop down menu in the **Power Cal Settings** dialog where it may be selected instead of a power sensor.

---

**Installation Calibration on a Banded Configuration**

The following describes the process for the installation and calibration when using banded 3rd party frequency extenders with a PNA/PNA-X that is connected via a N5292A test controller.

This is to ensure that when the N5290/91A broadband is used with the N5290A304 1.8m cable adapter the system is optimized for the best power levels being applied to the RF and LO of the external modules. In addition, it will ensure that we have a calibrated IF channel for accurate raw receiver measurements that require this level of accuracy, like the Spectrum Analysis application.

Note that the above calibration and installation process optimized for use with supported VDI and OML frequency extenders. While other Frequency extenders maybe used, they should at minimum
comply to the requirements as follows:

1. Nominal RF saturated power requirement of 10 dBm +/- 4 dBm. (9.2GHz-21.3GHz).
2. Nominal LO saturated power requirement of 10 dBm +/- 3 dBm. (9.2GHz-21.3GHz).
3. The IF level should be optimized for an operation of 7.606 MHz and not exceed the -20 dBm.

**System Hardware**

In the description we will use the following hardware:

1. N5247B
2. N5292A Test Set Controller
3. WR-10 3rd party frequency extenders

**Required Calibration Hardware**

The process would require at least a 26.5 GHz power sensor and adapter to complete.

**Overall Process**

1. Connect the PNA-X, controller and attach the N5290A304 cable adapters
2. Do not connect the frequency extenders to the N5290304A cable adapters
3. Connect the power sensor to the PNA-X
4. Configure the power sensor for measurements
5. Use the millimeter Wave Configuration Dialog to configure the modules.
6. Select the installation menu to start the calibration of the system
7. Complete the calibration steps, for optimal performance all steps should be completed.

**Procedure**

The following set of descriptions are intended to walk through the individual steps needed to complete the calibration of the banded setup.

**Millimeter Wave Dialog**
1. Assign a name to the configuration. In this example we use “WR10 Module”.
2. Assign the ports on the N5292A to which the Frequency extenders will be connected.
3. Set the RF and LO Multipliers, 6 and 8 in this example.
4. Assign Test Set to be a N5292A and the ports for the modules to be connected.
5. Click the **Installation Cal...** button. The following dialog will appear.
The 3 Cals should run in the order shown: LO first, RF second, IF third.

LO Calibration

Before starting the LO calibration, disconnect the (Test Set to PNA) rear panel LO cable from the PNA. The Banded LO Cal requires a 3.5 mm Power Sensor to be connected to the PNA rear panel LO connector.

1. In the Banded Installation CAL window, click **Begin LO**. The following dialog box will appear.
2. Leave the system default settings and complete the LO calibration.
4. Connect the Power Sensor to the PNA Rear Panel LO as shown below.

5. Click **Begin** to run the LO Calibration. It will complete in less than a minute. When done, disconnect the
Power Sensor from the PNA rear panel and reconnect the Test Set LO Cable.

6. Optionally, you can run the LO CAL Verify by clicking on the **Verify** button.
   - The first (bottom) trace shows LO Power without the Cal applied.
   - The second (top) trace shows LO power after the Cal is applied.
Overlap is normal for frequencies less than 8 GHz and greater than 22 GHz.

RF Calibration

1. In the Banded Installation CAL window, click **Begin RF**. The following dialog box will appear.
2. Select the Power meter and complete the calibration by connecting the power sensor to the end of the N5290A304 adapter cable RF cable as shown below.

3. Click **Exit** when done with the RF Cal.
IF Calibration

1. Turn off the N5292A controller and connect up all the banded modules.
2. Turn on the controller and leave all ports open.
3. Connect all the LO and RF cables to the modules.
4. In the Banded Installation CAL window, click **Begin IF**. The following dialog box will appear.

5. Once complete the system will be optimized for the best settings to be used by the banded system configured.
Broadband System Measurement Setup

Broadband refers to mmWave configurations with a frequency range of 900 Hz to 110 GHz (N5290A) or 900 Hz to 120 GHz (N5291A). This configuration spans the entire frequency range in a single sweep.

After minimal setup shown below, the N5290A/91A functions the same as a standard VNA. All ports can be used at mmWave frequencies or a combination as required.

In this topic:

- Limitations
- Setting Up a Measurement

Limitations

- ONLY the applications listed in Supported Applications are supported
- No automatic power leveling. However, after performing an Installation Calibration, the source power at the output of the N5293A or N5295A Frequency Extender is adjusted.
- Simultaneous broadband and banded measurements NOT supported
- Applications that require the use of source and receiver attenuators DO NOT apply to a millimeter wave system

See Also

- Supported Applications
- Supported Configurations
- Low Frequency Extension (LFE)

Setting Up a Measurement

1. Press Setup > External Hardware > Millimeter Config.
2. Select N5291A Broadband (or N5290A Broadband).
3. Note the ports selected for **Enable Modules**. Frequency Extenders connected to the test set are automatically detected. Configure as necessary.

4. Press **OK**. This closes the dialog.

5. To change the start frequency below 10 MHz (minimum of 900 Hz), press **Freq > Main > Start** then enter the start frequency below 10 MHz. The following dialog is displayed.

6. Click **OK**.

7. To change the stop frequency, press **Freq > Main > Stop** then enter the stop frequency.
Banded System Measurement Setup

Banded refers to any configuration that is not a broadband configuration and is waveguide based. Frequency extenders cover frequency ranges from 50 GHz to 1.1 THz. The supported solutions can be configured for different frequency bands with the N5292A Test Set controller depending on the measurements required and the frequency extenders being used.

After minimal setup shown below, the N5290A/91A functions the same as a standard VNA. All ports can be used at mmWave frequencies or a combination as required.

The following table shows the waveguide designation equivalents.

Requirements

- N5292A Test Set
- DC Source to provide bias voltage to frequency extenders
- Option S93080A/B and 020
- Special adapter cable to connect between frequency extender and N5292A Test Set
- Source power calibration is required for ALL power related measurements with banded millimeter modules

Limitations
ONLY the applications listed in Supported Applications are supported

Banded measurements must use the N5292A Test Set

No DC power connector in N5292A Test Set to provide bias voltage to frequency extenders for banded measurements

No automatic power leveling. However, after performing an Installation Calibration, the source power at the output of the N5293A or N5295A Frequency Extender is adjustable.

Simultaneous broadband and banded measurements NOT supported

See Also

- Banded Millimeter Configuration Dialog
- Supported Applications
- Supported Configurations
- Low Frequency Extension (LFE)

Setting Up a Measurement

1. Press Setup > External Hardware > Millimeter Config.
2. Select a banded configuration.
3. Click **PNA RF Source** or **PNA LO Source** to launch the External Devices dialog where you can select an internal or external source to be used for the VNA RF source or VNA LO source.

4. Set the appropriate **Multiplier** values that are specified in your mmWave module documentation.

5. In the **Test Port Frequency** fields, set the **Start** and **Stop** frequencies.

6. Ensure that the RF and LO Frequencies are within the frequency range of the sources. The VNA offers no warning if they are NOT.

7. Press **OK**. This closes the dialog.
Mixer Measurement Configuration

Mixer measurements can be made at mmWave frequencies using SMC. (VMC measurements are NOT supported. See Supported Applications.)

In this topic:

- Requirements
- Limitations
- Hardware Connections
- Procedure
- Measuring Harmonic Mixers
- SMC Calibration

See Also

- SMC Measurements
- SMC mixer setup dialog
- Supported Applications

Requirements

- For 2-port VNAs, connect External Source to the VNA GPIB Controller port. Learn how to Configure an External Source.
- Connect the 10 MHz reference signal of an external source to the VNA

Limitations

- 2-port systems require external source for LO
- VMC measurements are NOT supported

Hardware Connections

Connections with a 4-port mmWave system

Upconverters

- DUT Input - Connect to Standard VNA port 2 or port 4.
- DUT LO - Connect mmWave module to test set Port 3.
- DUT Output - Connect mmWave module to test set Port 1.

**Downconverters**

- DUT Input - Connect mmWave module to test set Port 1.
- DUT LO - Connect mmWave module to test set Port 3.
- DUT Output - Connect to Standard VNA port 2 or port 4.

**Connections with a 2-port mmWave system**

**Upconverters** - requires a mmWave module as a **source** at the DUT LO and a mmWave module as a **receiver** at the DUT Output:

- DUT Input - Connect to Standard VNA port 2.
- DUT LO - Connect the RF cable of the mmWave module to an external source or the VNA (SRC2) second source.
- DUT Output - Connect the mmWave module to the test set port 1.

**Downconverters** - requires two mmWave modules as **sources**

- DUT Input - Connect the mmWave module to the test set port 1.
- DUT LO - Connect the RF cable of the mmWave module to an external source or the VNA (SRC2) second source.
- DUT Output - Connect to Standard VNA port 2.

**Procedure**

1. Connect your DUT to the mmWave system as described in Hardware Connections.
2. Configure this dialog (Millimeter Module Configuration).
3. For banded mixer measurements only, check **Mixer Mode**.
4. Press **OK**. This presets the VNA.
5. Create an SMC measurement:
a. Press **Setup > Main > Meas Class....**

b. Select **SMC**, then either:

   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.

c. An SC21 measurement is displayed.

4. **Make mixer settings** in the same way as with standard SMC measurements. Only two DUT ports can be swept in frequency. The remaining DUT port must be a fixed frequency. [See configuration used for harmonic mixers.](#)

5. **Increase power** for mmWave modules that are connected directly to a VNA port or external source.

6. Calibrate using the **SMC Calibration**.

---

**Measuring Harmonic Mixers**

Harmonic mixers have a multiplier circuit in the LO port of the DUT. Enter the multiplier value in the numerator of the X LO port in the **SMC mixer setup dialog**. This will provide the correct LO frequencies out of the appropriate source.

**SMC Calibration**

With a configured SMC measurement active, perform the **Cal All Procedure**.
Troubleshooting the VNA

By running a few checks, you can identify if the analyzer is at fault. Before calling Keysight Technologies or returning the instrument for service, please make the following checks.

- Check the Basics
- VNA Application Terminates Unexpectedly
- Check Error Terms
- Check the Service Guide
- Error Log

Other Support Topics

Check the Basics

A problem can often be solved by repeating the procedure you were following when the problem occurred. Before calling Keysight Technologies or returning the instrument for service, please make the following checks:

**Note:** Problems with the VNA application (slow or terminates unexpectedly) can be caused by a faulty Hard Disk Drive (HDD). For more information, see Preventing VNA SSD Problems and The VNA SSD Recovery Process.

1. Is there power at the power socket? Is the instrument plugged in?

2. Is the instrument turned on? Check to see if the front panel line switch and at least one of the LED rings around the test ports glows green. This indicates the power supply is on.

3. If you are experiencing difficulty with the front-panel keypad or peripherals, the USB bus may be overloaded. Remove the USB devices, restart the VNA, and reconnect the USB devices. See Power-up.

4. If other equipment, cables, and connectors are being used with the instrument, make sure they are connected properly and operating correctly.

5. Review the procedure for the measurement being performed when the problem appeared. Are all the settings correct?

6. If the instrument is not functioning as expected, return the unit to a known state by pressing the Preset key.
7. Is the measurement being performed, and the results that are expected, within the specifications and capabilities of the instrument?

8. If the problem is thought to be due to firmware, check to see if the instrument has the latest firmware before starting the troubleshooting procedure.

9. Check that the measurement calibration is valid. See Accurate Measurement Calibrations for more information.

11. **Phase lock lost message** - This usually occurs when there is not enough source power to phase lock the VNA. It can occur during an errant FCA setup or Source Power Calibration. It can also occur if one of the front panel reference channel loops is not connected. Otherwise, this indicates a hardware problem.

---

### VNA Application Terminates Unexpectedly

If an unexpected and irrecoverable error occurs, Keysight would like to know about it. The VNA attempts to save pertinent information about the state of the system. **The VNA does NOT send this information to Keysight.**

We respect the privacy of our customers. However, access to information that helps us improve the VNA is a benefit to both Keysight and you. Please take the time to contact us or email the saved information to www.keysight.com/find/contactus.

The following procedure shows how to do this:

1. A message box immediately appears on the screen containing the location of a directory. Please record this message. If you miss the message, you can find the directory location using the Windows Event Log: On the VNA, click Start, Settings, Control Panel, Administrative Tools, Event Viewer. Double-click the top line (most recent event). The location of the directory is seen in the Description.

2. A dialog box may appear on the screen allowing you to add comments to help us replicate the crash.

3. Find the directory (described in Step 1) which contains the following files:

   - **835x.dmp** which is the 835x.exe capturing the context in which the program crashed.
   - **835x.xml** which reports some very basic information (exception code, OS version, and the list of modules loaded at the time of the crash and their respective version numbers).
   - **835xCrashLog.txt**: The text file with your comments (described in Step 2), if submitted.

4. If your VNA is not connected to LAN or is not configured to send email, copy the files to a PC. Then, please...
Check Error Terms

If you print the error terms at set intervals (weekly, monthly, and so forth), you can compare current error terms to these records. A stable, repeatable system should generate repeatable error terms over long time intervals, for example, six months. If a subtle failure or mild performance problem is suspected, the magnitude of the error terms should be compared against values generated previously with the same instrument and calibration kit. See the procedure for monitoring error terms.

- A long-term trend often reflects drift, connector and cable wear, or gradual degradation, indicating the need for further investigation and preventative maintenance. Yet, the system may still conform to specifications. The cure is often as simple as cleaning and gaging connectors or inspecting cables.
- A sudden shift in error terms reflects a sudden shift in systematic errors, and may indicate the need for further troubleshooting.

Consider the following while troubleshooting:

- All parts of the system, including cables and calibration devices, can contribute to systematic errors and impact the error terms.
- Connectors must be clean and gauged, and within specification for error term analysis to be meaningful. See the Chapter 2 in the VNA Service Guide for information on cleaning and gaging connectors.
  - Avoid unnecessary bending and flexing of the cables following measurement calibration, thus minimizing cable instability errors.
  - Use good connection techniques during the measurement calibration. The connector interface must be repeatable. See the VNA Service Guide for information on connection techniques.
- It is often worthwhile to perform the procedure twice (using two distinct measurement calibrations) to establish the degree of repeatability. If the results do not seem repeatable, check all connectors and cables.
- Use error-term analysis to troubleshoot minor, subtle performance problems. See Chapter 3, "Troubleshooting," in the VNA Service Guide if a blatant failure or gross measurement error is evident.

Check the Service Guide

Check the VNA Service Guide for specific troubleshooting procedures to help identify problems. You can download a copy of the Service Guide from our Web site: www.keysight.com/manuals/pna

Error Log
Some VNAs create automatic log of data for troubleshooting purpose. The log file stores data related to the total power ON time, number of times of power ON, results of power ON test and so on. For security reasons, if this data needs to be deleted, then `SERVice:LOGGing:CLEar` command can be used to clear the log recorded by the instrument.
Analyzer Error Messages

- 500 - 750 Calibrate
- 770 - 1000 Hardware
- 1000 - 1200 Measure
- 1281 - 1535 Parser
- 1536 - 1650 Display
- 1700 - 2000 Channel
- 2001 - 3021 General
- Standard SCPI Errors

Note: The EventID's listed below are provided for COM programming. For more information, see Working with analyzer Events

See Also: About Error Messages

Memory Overflow Error

Memory overflow. Trigger state set to Hold. Lower the IF bandwidth, or increase dwell or sweep time.

Severity: Informational

Further explanation: The measurement that you are currently making requires that data be stored faster than it can be processed. Very few customers will experience this situation.

Suggestions: To limit the amount of data to be stored, try lowering the IF Bandwidth, slow the sweep time, increase the dwell time, or limit the number of data points. There are many other settings that can be adjusted to solve this problem.

EventID:

Cal Errors

Message: 512

"A secondary parameter (power, IFBW, sweep time, step mode)of the calibrated state has changed."
Severity: Informational

Further explanation: The calibration is questionable when any of these secondary parameters change after the calibration is performed.

Suggestions: If you require an accurate measurement with the new settings, repeat the calibration.

EventID: 68020200 (hex)

Message: 513
"Calibration cannot be completed until you have measured all the necessary standards for your selected Cal Type."

Severity: Informational

Further explanation: You probably received this message because you attempted to turn correction on without first measuring all of the calibration standards

Suggestions: Finish measuring the cal standards

EventID: 68020201 (hex)

Message: 514
"Calibration set has been recalled using a file previously saved on an analyzer that had a different hardware configuration."

Severity: Informational

Further explanation:

Suggestions:

EventID: 68020202 (hex)

Message: 515
"Calibration is required before correction can be turned on. Channel number is <x>, Measurement is <x>.

Severity: Informational

Further explanation: There are no error correction terms to apply for the specified channel and measurement.

Suggestions: Perform or recall a calibration
EventID: 68020203 (hex)

Message: 516

"Critical parameters in your current instrument state do not match the parameters for the calibration set, therefore correction has been turned off. The critical instrument state parameters are sweep type, start frequency, frequency span, and number of points."

Severity: Informational

Further explanation: None

Suggestions: You can either recalibrate using the new settings or change back to the original setting that was used when the calibration was performed.

EventID: 68020204 (hex)

Message: 517

"Interpolation is turned off and you have changed the stimulus settings of the original calibration, so correction has been turned off."

Severity: Informational

Further explanation: The most accurate calibration is maintained only when the original stimulus settings are used.

Suggestions: If reduced accuracy is OK, set interpolation ON to allow stimulus setting changes.

EventID: 68020205 (hex)

Message: 518

"Interpolation is turned off and you have selected correction ON. Correction has been restored with the previous stimulus settings."

Severity: Informational

Further explanation: None

Suggestions: None

EventID: 68020206 (hex)

Message: 519

"Stimulus settings for your current instrument state exceeded the parameters of the original calibration,"
so correction has been turned off."

Severity: Informational

Further explanation: Correction data outside the stimulus settings does not exist.

Suggestions: Perform a broadband calibration, with increased numbers of points with interpolation ON, to maintain calibration over the widest possible stimulus frequency settings.

EventID: 68020207 (hex)

Message: 520

"Cal Type is set to NONE for Channel <x>, Measurement <x>; please select Calibration menu or press Cal hard key."

Severity: Informational

Further explanation: A cal operation can not proceed until a calibration exists or the cal type is selected. This error can occur if the calibration can not be found. Also this error can happen if a calibration type is not specified before attempting to programmatically execute cal acquisitions.

Suggestions To find a calibration, select a Cal Set that contains the calibration needed for the current measurements. OR specify the cal type before beginning a calibration procedure.

EventID: 68020208 (hex)

Message: 521

"The measurement you set up does not have a corresponding calibration type, so correction has been turned off or is not permitted."

Severity: Informational

Further explanation: The calibration for the channel may apply only to certain S-Parameters. For example, a 1-Port calibration for S11 can not be applied to a 1-Port calibration applied to S22.

Suggestions: Select a calibration type, such as full 2-Port cal, that can be applied to all the measurements to be selected.

EventID: 68020209 (hex)

Message: 522

"The calibration type you selected cannot be set up."

Severity: Informational
Further explanation: "Please use the SCPI command ROUTe:PATH:DEFine:PORT <num>,<num> for full 2 port type port assignment."

Suggestions:

EventID: 6802020A (hex)

Message: 523

"The calibration path you selected cannot be set up because it is not valid for the current measurement."

Severity: Informational

Further explanation: "Please use the SCPI command ROUTe:PATH:DEFine:PORT <num>,<num> for full 2 port type port assignment related to your current measurement."

Suggestions:

EventID: 6802020B (hex)

Message: 524

"The source power calibration is complete."

Severity: Informational

Further explanation:

Suggestions:

EventID: 6802020C (hex)

Message: 525

"You have specified more than 7 standards for one or more calibration classes."

Severity: Informational

Further explanation: These have been truncated to 7 selections.

EventID: 6802020D (hex)

Message: 526

"No user calibration found for this channel."

Severity: Informational
**Further explanation:** A cal operation can not proceed until a calibration exists.

**Suggestions:** To find a calibration, you can select a Cal Set that contains the calibration needed for the current measurement.

**EventID:** 6802020E (hex)

**Message:** 527

"You do not need to acquire this standard for this calibration type."

**Severity:** Informational

Further explanation: This error can happen as a result of PROGRAMMATICALLY requesting the measurement of an un-needed calibration standard during a calibration procedure.

**Suggestions:** Check the specified cal type or eliminate the request for the measurement of the standard.

**EventID:** 6802020F (hex)

**Message:** 528

"Could not configure the Electronic Calibration system. Check to see if the module is plugged into the proper connector."

**Severity:** Informational

Further explanation: During an ECal operation, communication could not be established with the ECal module. The calibration will not be initiated until the presence of the ECal module is verified.

**Suggestions:** Verify the USB cable is connected properly. Disconnect and re-connect the cable to ensure the analyzer recognizes the module.

**EventID:** 68020210 (hex)

**Message:** 529

"DATA OUT OF RANGE: Design Limits Exceeded"

**Severity:** Error

**Further explanation:**

**Suggestions:**

**EventID:** E8020211(hex)

**Message:** 530
"EXECUTION ERROR: Could not open ECal module memory backup file"

EventID: E8020219 (hex)

Message: 538

"EXECUTION ERROR: Cannot WRITE module"
Severity: Error

Further explanation:

Suggestions:

EventID: E802021A (hex)

Message: 539

"EXECUTION ERROR: Entry Not Found"

Severity: Error

Further explanation:

Suggestions:

EventID: E802021B (hex)

Message: 540

"EXECUTION ERROR: Invalid command while system is busy"

Severity: Error

Further explanation:

Suggestions:

EventID: E802021C (hex)

Message: 541

"Electronic Cal: Unable to orient ECal module. Please ensure the module is connected to the necessary measurement ports."

Severity: Error

Further explanation: There is no RF connection to the ECal module during a calibration step. An ECal orientation measurement has been attempted but the signal was not found.

Suggestions: Connect the ECal module RF connections to ports specified for the calibration step. The ECal module typically requires at least -18dBm for measurements. If your measurement requires the power level to be less than that, clear the **Do orientation** checkbox to bypass the automatic detection step.
EventID: E802021D (hex)

Message: 542
"EXECUTION ERROR: NO SPACE for NEW CAL, DELETE A CAL"

Severity: Error

Further explanation:

Suggestions:

EventID: E802021E (hex)

Message: 592
Severity: Informational
"No source power calibration found for the channel and source port of the current measurement."

Further explanation: You tried to turn on source power cal but there is no source power cal data.

Suggestions: Perform a source power calibration

EventID: 68020250 (hex)

Message: 593
Severity: Informational

"A source power calibration sweep was not performed, so there is no correction for the channel and source port of the current measurement."

Further explanation: You tried to turn on source power cal but there is incomplete source cal data.

Suggestions: Perform a complete source power calibration

EventID: 68020251 (hex)

Message: 594

Severity: Informational

"A new trace could not be added to the active window for viewing the source power cal sweep, because it would have exceeded the limit on number of traces/window. Please remove a trace from the window before proceeding with source power cal."

Further explanation: The source power cal attempts to add a data trace to the active window. The active window already contains four traces.

Suggestions: Make the active window contain less than trace limit.

EventID: 68020252 (hex)

Message: 595

Severity: Informational

"A new measurement could not be added for performing the source power cal sweep, because the limit on number of measurements has been reached. Please remove a measurement before proceeding with source power cal."

Further explanation: The source power cal attempts to add a measurement. The analyzer already has the maximum number of measurements.

Suggestions: Delete a measurement.

EventID: 68020253 (hex)

Message: 596

Severity: Informational

"The calibration power value associated with the source power calibration of Port %1 on Channel %2 was changed with the calibration on. The calibration was not turned off, but the power value might no
longer represent the calibration."

**Further explanation:** The source power cal accuracy is questionable.

**Suggestions:** If high accuracy is required, perform another source power calibration.

**EventID:** 68020254 (hex)

**Message:** 597

**Severity:** Informational

- Message that is passed from the power meter driver for a source power calibration. -

**Further explanation:** This error is generated by the power meter driver and passed through the analyzer.

**EventID:** 68020255 (hex)

**Message:** 598

"During the acquisition of the sliding load standard, the slide was not properly moved to perform a circle fit. The standard's raw impedance was used to determine the directivity for one or more points."

**Severity:** Informational

**Further Explanation:** To accurately characterize the standard, the sliding load must be move sufficiently to ensure enough samples around the complex circle or Smith Chart. Under-sampling will cause an inaccurate result.

**Suggestions:** For best results when using a sliding load, be sure to use multiple slide positions that cover the full range of movement from front to back of the slot.

**EventID:** 68020256 (hex)

**Message:** 599

"This feature requires an unused channel, but could not find one. Please free up a channel and try again."

**Severity:** Informational

**Further Explanation:** You attempted to view an item within a calset. However, the calset viewer requires that the result be displayed in a channel that is not currently in use. All the channels are currently used. The view can not display the requested item.

**Suggestions:** You must delete at least one channel that is currently in use.
EventID: 68020257 (hex)

Message: 600

"Interpolation of the original calibration is not allowed since it was performed using Segment Sweep. Correction has been turned off."

Severity: Informational

EventID: 68020258 (hex)

Message: 601

"Cal preferences saved. Cal preference settings can be changed from the 'Cal Preferences' drop down Cal menu."

Severity: Informational

EventID: 68020259 (hex)

Message: 608

"CalType not set."

Severity: Error

Further explanation: A cal operation can not proceed until a calibration exists or the proper cal type is selected.

Suggestions: This error can happen if the calibration can't be found. To find a calibration, you can select a Cal Set that contains the calibration needed for the current measurements. This error can also happen if a calibration type is not specified before attempting to programmatically execute cal acquisitions. Specify the cal type before beginning a calibration procedure.

EventID: E8020260 (hex)

Message: 609

"The Calibration feature requested is not implemented."

Further explanation: The specified cal type can be one of many choices. For example, response calibrations require single standards, 1-Port calibrations require 3 standards, and 2-Port calibrations require up to 12 standards.

Suggestions: Be sure to measure only the standards needed for the specified cal type.

EventID: E8020261 (hex)
**Message: 610**

"The Calibration Class Acquisition requested is not valid for the selected Calibration Type. Please select a different acquisition or a different Calibration Type."

**EventID:** E8020262 (hex)

**Message: 611**

"The Calibration Standard data required for the selected caltype was not found."

**Severity:** Error

**Further explanation:** An unsuccessful attempt was made to retrieve a specified standard from the raw measurement buffer. The buffer should contain the raw measurements of cal standards stored during a calibration procedure.

**Suggestions:** Be sure the requested standard is required for the current cal type. Not all standards are needed for all cal types.

**EventID:** E8020263 (hex)

**Message: 612**

" The Error Term data required for the selected caltype was not found."

**Severity:** Error

**Further explanation:** An unsuccessful attempt was made to retrieve a specified error term from the error correction buffer. The buffer should contain the error correction arrays for the current calibration.

**Suggestions:** Be sure the requested error term is required for the current cal type. Not all error terms are needed for all cal types.

**EventID:** E8020264 (hex)

**Message: 613**

The Calibration data set was not found.

**Severity:** Error

**Further explanation:** An unsuccessful attempt to access a cal set has been made. This may indicate a calset has been deleted or has been corrupted.

**Suggestions:** Try again or select another cal set. If the cal set appears in the cal set list, it may need to be deleted.
EventID: E8020265 (hex)

**Message: 614**

"The specified measurement does not have a calibration valid for Confidence Check. Please select a different measurement, or recall or perform a different Calibration Type."

**Severity:** Error

**Further explanation:** The measurement choice is prevented so that calibration will not be turned off. Not all cal types support all measurements. For example, an 1-Port cal on S11 can not be used to calibrate an S12 measurement. When a measurement is selected that does not have a calibration which can be applied, an informational message is displayed and calibration is turned off.

**Suggestions:** Use a full 2-Port calibration to be compatible with any S-Parameter.

EventID: E8020266 (hex)

**Message: 615**

" New calset created."

**Severity:** Informational message.

**Further explanation:** The newly created cal set will be automatically named and time stamped. If this is the beginning of a calibration procedure, the cal set will not be stored to memory until the calibration has completed successfully. The new cal set will be deleted if the calibration is canceled or does not otherwise complete successfully.

**Suggestions:** Informational

EventID: 68020267

**Message: 617**

The calset file: <x> appears to be corrupted and cannot be removed. Exit the application, remove the file, and restart.

**Severity:** Error

**Suggestions:** The cal set file is stored in the application home directory D:\analyzerCalSets.dat. Remove this file, then restart the application.
"The calset file: <x> load failed."

**Severity:** Error

**Further explanation:** The calset file contains a collection of calsets. The file resides on the hard drive.

**Suggestions:** Try restarting the application. If the failure persists, you may have to delete the cal set data file and restart the application. The cal set file is stored in the application home directory. D:\analyzerCalSets.dat. Remove this file, then restart the application.

**EventID:** E802027A (hex)

**Message:** 635

"The calset file: <x> save failed."

**Severity:** Error

**Further explanation:** The file operation detected an error. The save operation was aborted.

**Suggestions:** Retry.

**EventID:** E802027B (hex)

**Message:** 636

"A calset was deleted."

**Severity:** Informational

**Further explanation:** One of the calsets has been successfully deleted from the collection of calsets available. This can happen as the result of a user request or intentional operation.

**Suggestions:** None

**EventID:** 6802027C (hex)

**Message:** 637

"The version of the calset file: <x> is not compatible with the current instrument."

**Severity:** Error

**Further explanation:** A versioning error can prevent a calset from being used. This can happen as a result of instrument firmware upgrades.

**Suggestions:** If the versioning error is the result of firmware upgrade, you will have to re-install the old version of firmware to re-use the calset file. Or you can re-create the calsets with the current
version of firmware.

The cal set file is stored in the application home directory D:\analyzerCalSets.dat. Remove this file, then restart the application.

**EventID:** E802027D (hex)

**Message:** 638

"Incompatible CalSets found: \(<x>\) of \(<y>\) stored calsets have been loaded."

**Severity:** Error

**Further explanation:** Errors were found on some of the calsets stored in the calset file. The errors may have been caused by versioning issues that may have corrupted the various calset keys.

**Suggestions:** Use the calset viewer to look at the contents of calset files. Delete the files that are corrupted.

**EventID:** 6802027E (hex)

**Message:** 639

"The Calset file: \(<x>\) was not found. A new file has been created."

**Severity:** Informational

**Further explanation:** The calset file should be stored on the hard drive. When the application is started, a search is done and the file is loaded if it can be found. If the file is not found, the analyzer will create a new file and display this message.

**Suggestions:** None

**EventID:** 6802027F (hex)

**Message:** 640

"The Calset specified is currently in use."

**Severity:** Error

**Further explanation:** This may indicate a conflict between multiple calset users attempting calibration tasks.

**Suggestions:** Save the instrument state. Preset the analyzer and recall the instrument state. This may abort any processes that may be in progress.
EventID: E8020280 (hex)

Message: 641
"The calset specified has not been opened."

Severity: Error

Further explanation: Multiple users may be attempting to access the calset.

Suggestions: Close multiple calset users so that only one user will access the calset.

EventID: E8020281 (hex)

Message: 642
"The maximum number of cal sets has been reached. Delete old or unused cal sets before attempting to create new ones."

Severity: Error

Suggestions: You may also delete the calsets data file.

The cal set file is stored in the application home directory. D:\analyzerCalSets.dat. Remove this file, then restart the application.

EventID: E8020282 (hex)

Message: 643
The requested power loss table segment was not found.

Severity: Error

EventID: E8020283 (hex)

Message: 644
"A valid calibration is required before correction can be turned on."

Severity: Error

Further explanation: This usually indicates a calibration procedure has not run to completion or that the selected measurement does not have a valid calibration available from within the currently selected cal set.

Suggestions: To find a calibration, you can select a Cal Set that contains the calibration needed for the current measurements. This error can happen if a calibration type is not specified before attempting to
programmatically execute cal acquisitions. Specify the cal type before beginning a calibration procedure.

**EventID:** E8020284 (hex)

**Message: 645**

The cal data for <x> is incompatible and was not restored. Please recalibrate.

**Severity:** Warning

**Further explanation:** None

**Suggestions:** None

**EventID:** A8020285 (hex)

**Message: 646**

"CalSet not loaded, version is too new."

**Severity:** Error

**Further explanation:** An old version of firmware is attempting to run with a new calset version. The version is incompatible.

**Suggestions:** The calset can be removed. You may also delete the calsets data file if you are migrating between various firmware revisions often and you would like to avoid this error. The cal set file is stored in the application home directory. D:\analyzerCalSets.dat. Remove this file, then restart the application.

"Measurement not found."

Severity: Error
Further explanation: Any of these could be the cause:

Trying to calibrate but already have maximum measurements.

Trying to do a confidence check but there is not a measurement.

Trying to create, activate, or alter a measurement through COM that has been deleted through the front panel.

Trying to use a trace name through programming that is not unique.

EventID: E8040452 (hex)

Message: 1107

"No valid memory trace."

Severity: Error

Further explanation: Must have a memory trace when trying to do Trace Math,

Suggestions: Store a memory trace.

EventID: E8040453 (hex)

Message: 1108

"The reference marker was not found."

Severity: Error

Further explanation: Attempted to create a delta marker without first creating a reference marker (COM only).

EventID: E8040454 (hex)

Message: 1109

"Data and Memory traces are no longer compatible. Trace Math has been turned off."

Severity: Error

Further explanation: Warning - channel setting has changed while doing trace math.

Suggestions: Store another memory trace and turn trace math back on.

EventID: A8040455 (hex)
Message: 1110

"Data and Memory traces are not compatible. For valid trace math operations, memory and data traces must have similar measurement conditions."

Severity: Error

Further explanation: Tried to do trace math without compatible data and memory traces.

Suggestions: Store another memory trace.

EventID: E8040456 (hex)

Message: 1111

"Marker Bandwidth not found."

Severity: Error

Further explanation: Could not find a portion of trace that meets the specified bandwidth criteria.

EventID: E8040457 (hex)

Message: 1112

"The peak was not found."

Severity: Error

Further explanation: Could not find portion of trace that meets peak criteria.

Suggestions: See Marker Peak criteria.

EventID: E8040458 (hex)

Message: 1113

"The target search value was not found."

Severity: Error

Further explanation: Could not find interpolated data point that meets search value.

EventID: E8040459 (hex)

Message: 1114

Further explanation: A non-existent channel is being referenced under program control.
Suggestions: Query the channel number, then refer to it by number.
EventID: E8070750 (hex)

Message: 1873
"The requested sweep segment was not found."
Severity: Error
Further explanation: A non-existent sweep segment is being referenced under program control.
EventID: E8070751 (hex)

Message: 1874
"The sweep segment list is empty."
Severity: Error
Further explanation: Segment Sweep cannot be specified unless there is at least one defined segment. This error will only occur under remote control.
EventID: E8070752 (hex)

Message: 1875
"The number of points in active sweep segment list segments is 0."
Severity: Error
Further explanation: Segment Sweep cannot be specified unless there is at least data point specified
in a segment. This error will only occur under remote control.

**EventID:** E8070753 (hex)

**Message:** 1876

"The specified source attenuator is not valid."

**Severity:** Error

**Further explanation:** You tried to set the Attenuator property on the Channel object on a analyzer that doesn't have a source attenuator.

**EventID:** E8070754 (hex)

**Message:** 1877

"Log Frequency sweep cannot be selected with the current Number of Points. Please reduce Number of Points."

**Severity:** Error

**Further explanation:** The maximum number of points that can be used for Log sweep is 401.

**EventID:** E8070755 (hex)

**Message:** 1878

"The requested Number of Points is greater than can be selected for Log Frequency sweep."

**Severity:** Error

**Further explanation:** The maximum number of points that can be used for Log sweep is 401.

**EventID:** E8070756 (hex)

**Message:** 1879

"Response frequencies exceeded instrument range so Frequency Offset has been turned off."

**Severity:** Error

**Further explanation:** This error is returned whenever the instrument detects that the stimulus sweep setup and Frequency Offset settings result in computed response frequencies that exceed instrument limits. When this occurs, the instrument automatically turns off Frequency Offset to avoid the out-of-range conditions.

**Suggestions:** When this condition has occurred, change settings for either the stimulus frequencies or
Frequency Offset so that the Response frequencies are within instrument bounds. Once this is done, Frequency Offset can once again be turned on.

**EventID:** E8070757 (hex)

**Message:** 1880

The total number of points for all the given segments exceeds the maximum number of points supported. The segments were not changed.

About Error Messages

Analyzer errors and Operating System errors are displayed and logged in an error file. You can choose how to display errors, or choose to not display errors at all.

- Error Display
- View Error Log
- List of VNA Errors
- SCPI Errors

Other System topics

Error Display

By default, error messages appear on the screen for a brief period. You can choose to have them stay on the screen until you click an OK button, or have them not appear at all. When they stay on the screen, a Help button is available to provide further assistance.

How to select the display of Error Messages

Using Hardkey/SoftTab/Softkey

1. Press System > Help > Error Display....
On Preset, these settings revert to their defaults (enabled, timed popups).

**Enable Messages** Check to display all error messages as they occur. Clear to suppress the display of error messages. You can still view them in the error log.

**Calibration Error Message Windows**

- **Status bar Display** Displays error messages on the screen for a duration of time proportional to the length of the message. You can then view the message in the error log and get further assistance.

- **Confirmation Dialog boxes** Displays error messages in a standard dialog box. You then choose OK or Cancel to close the dialog box, or press Help to get further information on the error message.

**View Error Log**

The analyzer Error Log is a list of all events that have occurred. (Events are used in programming the analyzer using COM.) Analyzer errors are a subset of events. Only events with severity codes of ERROR are displayed on the screen as they occur. From the error log, you can access further help with an error by selecting the error and clicking Help.

**How to view the Error Log**

Using **Hardkey/SoftTab/Softkey**

1. Press **System > Help > View Error Log**....

**Error Log** dialog box help
Network analyzer errors only  Select to view only analyzer errors. Clear to view all errors that occur on all applications of the computer.

Description  Error message that appears on the analyzer screen.

A - Event ID  Error message number

B - Date the Error occurred

C - Time the Error occurred

D - Severity Code - All events have one of the following severity codes:

- SUCcess - the operation completed successfully
- INFormational - events that occur without impact on the measurement integrity
- WARning - events that occur with potential impact on measurement integrity
- ERRor - events that occur with serious impact on measurement integrity

E - Application in which the error occurred.

OK  Closes the Dialog box

Help  Provides further information on the selected Error message

To clear the Error Log:
1. From the **System > Main** menu click **Minimize Application**.

2. On the desktop, select **Start, Control Panel**

3. On the Control Panel, click **Administrative Tools**

4. On the Administrative Tools window, click **Event Viewer**

5. On the Event Viewer window, right-click **Application**

6. Select **Clear all Events**

7. If you want to save a file with the contents of the Event Log, click **Yes**. Otherwise, click **No**

To restore the VNA application, click on the VNA Analyzer taskbar button at the bottom of the screen.
Analyzer Accessories

- Coax Mechanical Calibration Kits
- Waveguide Mechanical Calibration Kits
- Electronic Calibration (ECal)
- Mechanical Verification Kits
- Adapter and Accessory Kits
- Test Port Cables
- USB Peripherals
- Connector Care and ESD Supplies

Other Support topics

For product and order information:

- Visit www.Keysight.com/find/accessories
- Use the search function to locate information about a particular accessory or view the entire RF and Microwave Test Accessories Catalog.

Accessories are available in these connector types:

- 50 ohm Type-N
- 75 ohm Type-N
- 3.5 mm
- 7 mm (APC-7)
- 7-16
- 2.92 mm
- 2.4 mm
Test port cables and a calibration kit are necessary for a complete measurement system.

A verification kit is used to verify corrected system performance.

See the connector type for each VNA model

The Keysight 82357B is an adapter that creates a GPIB Interface from one of your unused VNA USB ports.

**Applications**

The 82357B can be used to connect a GPIB device using the VNA USB for any VNA application. In addition, the 82357B can be used to connect a power meter for a source power calibration.

**Installing the 82357B USB/GPIB Interface**

1. Download and install firmware VNA revision 3.0 or greater. To check the revision of your VNA firmware, click Help then About Network Analyzer.

**Configure the 82357B USB/GPIB Interface**

When the 82357B is connected to the VNA USB, the driver is automatically installed.

Normally, you do NOT need to edit these settings. The 82357B USB/GPIB Interface is configured automatically as the next unused VISA interface. Keysight Connection Expert allows you to change the setting.

If the VISA Interface Name appears as GPIB0 or GPIB1, these Interfaces must be returned to their default settings for the 82357B to work properly with the VNA. See Configure for VISA / SICL to learn how.

**Connecting the 82357B USB/GPIB Interface**

The following diagram illustrates how to connect GPIB test equipment using the USB/GPIB Interface.
• Plug the USB/GPIB Interface into any unused VNA USB port.
• The driver installation and connection is performed automatically.

**Communicating with Equipment Connected to the USB/GPIB Interface**

• The Frequency Converter Application will automatically find and communicate with test equipment that is connected to the USB/GPIB Interface.

• Source power calibration: Select **GPIB** at the *Power Meter Settings* dialog and specify the GPIB address of the power meter.

• To control other devices through your own program using the 82357B, you must include the new GPIB Interface number when addressing the devices.
Firmware Update

VNA firmware updates are available to you at no cost in a self-extracting Install Shield file. The update includes the VNA application, Online help, and Service Utilities.

To manually check the version of firmware on the VNA, click **System > Help > About NA...**

**Tip:** Use **Move App to Back** to cause the VNA application to move behind this application on the screen.

The following options are available for you to update your VNA application:

- **Auto-Check and Firmware Update** If your VNA is connected to the Internet, these utilities will automatically check for, download, and install, the new firmware and associated files when the VNA application is started. You will be prompted before this occurs.

- **Website Access** If your VNA is NOT connected to the Internet, but you have a PC that is, you can download the VNA firmware and associated files to a storage medium.

**Note: After a firmware update...**

- Custom Cal Kits must be imported. Learn more

- If a different desktop icon named "Network Analyzer" exists, the shortcut to the VNA application will assume the same icon. Right-click on the desktop, then click **Refresh**.

**Other Support Topics**

**Auto-Check**

With Internet access to your VNA, Auto-Check automatically and regularly checks the Internet for new VNA firmware revisions. If a new revision is found, a notification message prompts you to run the **Firmware Update** utility, which then performs the actual download.

Without Internet access to your VNA, Auto-Check provides a reminder prompt at the selected intervals.

Auto-Check is run only when the VNA application is started. Once the VNA application is running, it will not check for updates again until it is restarted.

When Auto-Check runs, it checks the following conditions:
- Is there an active connection to the Internet?
- Is the Auto-Check utility enabled?
- Is it time to check for new firmware?
- Does new firmware exist?

If all of these conditions are true, Auto-Check shows the following dialog box.

If all of these conditions are NOT true, or to change these settings at any time, press **System**, then **Service**, then **Update Firmware**. From within the utility, click **AutoCheck**. These preferences are stored in the VNA registry. Future firmware updates will not change these settings.

---

**VNA Auto-Check** dialog box help

**Enable**  When the VNA application is started, Auto-Check will search the VNA website for firmware updates at the selected time interval.

**Disable**  When the VNA application is started, Auto-Check will NOT search the VNA website for firmware updates.

**Time Interval**  Select the time interval Auto-Check is to search for firmware updates.

**Accept**  Starts update process.

**Ignore**  No further action is taken until the selected time interval has elapsed.

**Remind Me Later:**  This window is displayed again after 1-20 days depending upon the time interval selected.

---

**Firmware Update Utility**
**How to start Firmware Update**

Connect the VNA to the Internet. A LAN connection is recommended because a firmware download can take many hours using a modem.

**Using Hardkey/SoftTab/Softkey**

1. Press **System > Service > Update Firmware**.

**Using a mouse**

1. Click **Utility**
2. Select **System**
3. Select **Service**
4. Select **Update Firmware**

1. Click **Check for Updates**.
2. If updates exist, click **Download & Install**.

---

**AgileUpdate** dialog box help

**Note:** Your privacy is important to Keysight. The update utility does NOT send ANY information from the VNA to the server. It only downloads from the server to the VNA.
**Restart**  Click to restart from the beginning.

**Configure**  Click to launch the Configure dialog box.

**Clean-up**  Click to delete all but the two most recent install shield packages from the VNA hard drive.

**Firmware History**  Available after clicking Check for Updates.

**Auto-Check**  Launches the Auto-Check dialog box.

**Item / Application**  Lists the items available for download at the firmware website.

- Click items with i to read more information about the download.
- Items in RED should be downloaded and installed individually.
- Multi-language help includes all help files except English.

**Note:** The firmware includes the help file. Therefore, only the firmware checkbox will be selected if a new version for both the firmware and the help file are available.

**Select Source**

**Default Website**  The Keysight site that contains update FW.

**Other Specified URL**  Click if you were instructed to get firmware from a different website.

**Check Customer FW Releases**  Check this box to also check Customer Releases in addition to Production Releases. This setting provides you with the very latest VNA firmware. Customer Releases are fully supported but have not yet been tested in all production models. Customer Releases take precedence over Production Releases. This setting is remembered and applied the next time update utility is run.

**Special Access Code...**  Type in the code if you were given one from Keysight Technical Support. Otherwise, leave blank.

**Make Latest Firmware Available...**  Select this checkbox if you want to download the latest firmware, even if it is not new.

**Check for Updates**  Click to look for firmware updates at the Keysight website. If there are newer versions, the files will be listed.

**Download and Install**  When updates are found, this selection becomes available. Some files may be pre-checked. Be sure the corresponding boxes are checked for the files you want to download.
Then click to download and install the update.

**Download Only**  Click to download the files to the analyzer hard disk and install the files at a later time. At that time, click Install from File.

---

### Configuration dialog box help

**Note:** If the update utility will not connect, try to access ANY Internet website. Contact your local IT department if necessary.

**Proxy Setting**

- **No Proxy or Default Proxy**  Click if you use a LAN connection. The update utility will automatically use the proxy specified in Internet Explorer.

- **Use specified Proxy / Port**  Click to enter the proxy name and port. The format is: `proxyName:portNumber`. (The proxy port number is typically 8088).

**Internet timeout**  If you are using an automatic dial-up Internet connection you may need to increase the timeout.

**Current Connection Status**  Shows the current status of the VNA connection to the Internet.

**Note:** These settings are NOT saved; they must be re-entered each time the update utility is run.

---

### Updating firmware

2. Terminate the VNA application by pressing System > Main > Exit.

3. Transfer the file from your PC to your VNA using LAN or USB Pen drive.

4. Double-click the file on the VNA and follow the instruction.

**Warning:** You can save the update file to your PC, but do not attempt to install the VNA application on your PC. It will alter system settings and can result in system crashes.
VNA Configurations and Options

Included with each VNA is a mouse and keyboard. This topic presents VNA models that are supported with this firmware release and the available options.

- PNA-X Series
- VNA N522xB Series
- VNA N523xB (Updated PNA-L) Series
- mmWave Model
- Measurement Receiver N5264B
- Common VNA Options
- Certification Options for ALL Models
- *OPT? and Options COM Behavior
- Warranty Period

See Also

- VNA Series Configuration Guide (requires an Internet connection)
- Click Help then About Network Analyzer to view the options that are installed on your VNA.

Other Support Topics

PNA-X Series

See Block Diagrams

- N5249B: 10 MHz to 8.5 GHz
- N5241B: 10 MHz to 13.5 GHz
- N5242B: 10 MHz to 26.5 GHz
- N5244B: 10 MHz to 43.5 GHz
- N5245B: 10 MHz to 50.0 GHz
- N5247B: 10 MHz to 67 GHz
- N5264B: Measurement Receiver [Learn more]

**PNA-X Options**

See other options that MAY be offered on the PNA-X models

See [NVNA Brochure](#) for more PNA-X options.

**PNA N522xB Series**

See Block Diagrams.

See Specs

- **N5221B**: 10 MHz to 13.5 GHz
- **N5222B**: 10 MHz to 26.5 GHz
- **N5224B**: 10 MHz to 43.5 GHz
- **N5225B**: 10 MHz to 50.0 GHz
- **N5227B**: 10 MHz to 67 GHz

The N522xB models are identical to the PNA-X series except:

- N522xB 2-port models are NOT available with 2 sources.
- N522xB option numbering is slightly different.
- N522xB models do NOT have internal RF switches or combiners (no RF Path Configuration). This has many measurement implications.
- N522xB models do NOT have rear-panel access to RF Paths.
- N522xB models do NOT offer a Noise Receiver (Opt S93029A/B).

**Options**

**108** - Built-in 26.5 GHz LO source with +10 dBm output power.

**S93118A/B** - Fast-CW mode enables 500 million point data buffer.

**Common Options**

The following options are common to more than one VNA family. For PNA-B model and E5080A which is shipped after Sep 2017, the software option is provided as a product number S93xxxA for PNA and S96xxxA for ENA(E5080A). The fixed, transportable, perpetual and time limitation options are available.

**Documentation**

**Description**

A documentation CD-ROM is no longer included with each VNA shipment (Feb.2005).

To download a service guide for your VNA, or the latest version of VNA Help, visit [www.Keysight.com/find/pna](http://www.Keysight.com/find/pna), search for your VNA model, then click Library.

**VNA Warranty Period**

The actual warranty on your instrument depends on the date it was ordered as well as whether or not any warranty options were purchased at that time. To determine the exact warranty on your instrument, contact Keysight Technologies with the model and serial number of your instrument.

For online information about Keysight's service and support products visit:
Option Enable

The software option can be installed by yourself. See https://www.keysight.com/find/LicensingSupport about detailed Keysight license information.

On your PC

2. Log in or register your name if first time log-in.

3. Click “You can add a new certificate”
4. Locate the **Software License Entitlement Certificate**.

5. Enter your “Order Number” and “Certificate Number” on Software Entitlement Certificate.

6. Follow the instructions to register the ordered software licenses.

7. Click “You can request new licenses”

8. Select your required license (ex. S9xxxxx)
9. Add your **HOST ID**.

**Node-locked / Transportable / Trial Licenses**

**PXI VNA / S9405xB Simulator**

Select the host to assign licenses to

- **Model Number**: PCSERNO
- **Serial Number**: FF7996258

**Bench Top VNA**

The license file can be copied to the root directory of the USB device and then connected to the VNA. The Keysight License Manager is always running, and it scans the root directory of any new drive looking for license files. When the file is found, the licenses are automatically installed, and a notification is displayed on the screen. If the licenses are not installed automatically, then the following instructions should be followed.
USB VNA

Floating License for all VNAs and Simulator

USB Portable License for all VNAs and Simulator

Click “Assign License” at the bottom.

10. Follow the instructions.

11. The message with license file (.lic) is sent to your email address.

On the analyzer or controller for analyzer

Node-locked / Transportable / Trial Licenses

Note: Do not install the floating/USB licenses on Keyight License Manager. Use Keysight License Manager 6 instead.

1. Execute the Keyight License Manager from Start Menu in Windows
2. Click “What if I have a license file to install”, then follow the instruction to install the license file.

Detailed instructions can also be found in the Keysight License Manager help.

**Floating License**

The floating license allows you to borrow/return the license from the license server. Your local controller can be a license server if required.

1. Make sure if the license has already been installed in the license server.

2. Execute the Keysight License Manager 6 as Administrator from Start Menu in Windows on the analyzer or controller for analyzer.

3. Click **Specify a remote floating license server**, then enter the host name or IP address of the license server.

4. Select **Borrow License** Tab, then click **Borrow a floating license**.

5. Select the required license and specify the return date.

6. Select **View License** Tab, then confirm if the selected license is installed.

Detailed instructions can also be found in the Keysight Licensing Administrator's Guide

Setup a license server

1. Download a Keysight License Manager 6 from https://www.keysight.com/find/LicensingSupport and install it on a PC which you will assign as a license server. If you want to use your controller as a server, the installation is not necessary. See next.

2. Execute the Keysight License Manager 6 as Administrator from Start Menu in Windows.

3. Click Add/remove a license on your local machine

4. Select Add license to the floating license serve to be used by other machines.

5. Click Browse… to select license file (.lic), then click Next.

6. Select View License Tab, then confirm if the selected license is installed.

Use your controller as a license server

The network connection is not required when your controller is used as a license server.

1. Execute the Keysight License Manager 6 as Administrator from Start Menu in Windows on the analyzer or controller for analyzer.

2. Click Add/remove a license on your local machine

3. Select Select a product to license and use on the machine.

4. Select PNA, ENA or PXIVNA. Select PXIVNA for USB VNA.

5. Click Browse… to select license file (.lic), then click Next.

6. Select View License Tab, then confirm if the selected license is installed.

Known Issue

When the VNA does not detect the floating license, execute the following procedure.

1. Execute C:\Windows\system32\services.msc and find EEsof EDA License Server.
2. If the status is either blank (Stopped) or status type is Automatic (Delayed Start), then right click and select **Properties**.

3. Change the status type from Automatic (Delayed Start) to Automatic, then click **Start** of the Service Status.
4. Confirm if the Status is changed to **Started** and **Automatic**.
USB Potable License

The application/option is enabled only when the analyzer or controller has both license and the corresponding USB dongle. A license file can be installed on many analyzers or controllers. The application is activated while the dongle is plugged in.

1. Execute the Keysight License Manager 6 as Administrator from Start Menu in Windows on the analyzer or controller for analyzer.

2. Click *Add/remove a license on your local machine*.

3. Select *Select a product to license and use on the machine*.

4. Select PNA, ENA or PXIVNA. Select PXIVNA for USB VNA.

5. Click *Browse…* to select license file (.lic), then click *Next*.

6. Select *View License* Tab, then confirm if the selected license is installed.

7. When you use the application on the analyzer, connect the dongle in the USB port to enable the capability for license.

*Note:* If your analyzer or controller does not detect the dongle, download and install the FLEXID10USBDriver package for your platform from https://www.keysight.com/find/LicensingUsbDriver.

Detailed instructions can also be found in the Keysight Licensing Administrator's Guide.

About HOST ID

The HOST ID will be asked when you get the license file.

Host ID for Fixed / Transportable / Trial Licenses
PXI VNA/ Bench Top VNA / Simulator

HOST ID is shown in the Keysight License Manager. Keyight License Manager can be executed from Start Menu in Windows.

The HOST ID syntax for Bench Top VNA is {Model No.},{Serial Number}

The HOST ID syntax for PXI VNA and S94050B/51B Simulator is PCSERNO, {two letters and eight
numbers (this is nothing related with PC serial number)
Host ID for Floating

HOST ID is Mac address

On the server machine, execute `getmac /v /fo list`. Your host ID is listed as the Physical Address of the Network Adapter.
Host ID for USB Portable

HOST ID is printed on a USB dongle.

The USB dongle can be ordered as an option of USB portable licence or Keysight P/N E8900-80036 Hardware Key-USB Port FLEX10.
Instrument Calibration

An instrument calibration is a process where the analyzer performance is measured to ensure that it operates within specifications. If any performance parameter does not conform to the published specifications, adjustments are made to bring the performance into conformance.

Why Should I Get an Instrument Calibrated?

Over time, the active components in the analyzer age and the performance may degrade or drift.

To ensure that the analyzer is performing to the published specifications, you should have an instrument calibration performed periodically.

How Often Should I Get an Instrument Calibrated?

It is your responsibility to determine the calibration period which best meets your requirements. However, a 12 to 18 month calibration cycle is appropriate for most users.

There are two things to consider: performance drift and connector wear.

- The instrument specifications are set to consider the performance drift that may occur over a 24 month period. Therefore, getting the instrument calibrated at 24 month intervals ensures that the analyzer maintains performance within the operating specifications. If you need the analyzer to maintain more consistent operation, you may want to have the instrument calibrated more often than the recommended 24-month interval.

- Connector wear is a bigger factor and depends on the number of connections that are made. The test ports become noticeably worn after 500 to 700 connections. This could represent about 12 months with average use. With more frequent connections, the calibration cycle should be sooner. You can extend the time between calibrations and thereby save money by using connector savers and by performing proper Connector Care.

How Do I Get an Instrument Calibrated?

To get the instrument calibrated, send it to one of the Keysight Technologies service centers. See Technical Support.

The analyzer must be fully functional when it is sent to the service center, or they will charge for their repair services. If the analyzer is being used in a secure environment where the hard drive can not be sent with the analyzer, a second hard drive must be purchased and configured for use with the analyzer in an "unclassified" environment before the analyzer is sent to the service center.

To perform the instrument calibration yourself, you must have the following required items:
What Are My Choices of Instrument Calibration?

The following types of instrument calibration are available from Keysight Technologies at the time of initial order:

**Standard**
Includes a certificate of calibration stating the instrument has been calibrated and is operating within the published specifications.

**Option UK6**
Available ONLY at the initial shipment. Includes the test data from the calibration and the certificate of calibration stating the instrument has been calibrated and is operating within the published specifications.

**Option A6J**
Available ONLY at the initial shipment. Includes the test data and measurement uncertainties from the calibration and the certificate of calibration stating the instrument has been calibrated using a process in compliance with ANSI Z540 and is operating within the published specifications.

**Option 1A7**
Available ONLY at the initial shipment. Includes the test data and measurement uncertainties from the calibration and the certificate of calibration stating the instrument has been calibrated using a process in compliance with ISO 17025 and is operating within the published specifications.

The following types of instrument calibration are available from Keysight Technologies service center:

**Keysight Calibration**
Includes the test data from the calibration and the certificate of calibration, stating the instrument has been calibrated and is operating within the published specifications.

**ANSI Z540 Calibration**
Includes the test data from the calibration and the certificate of calibration, stating the instrument has been calibrated using a process in compliance with ANSI Z540.1 and is operating within the published specifications.

**ISO 17025 Calibration**
Includes the test data from the calibration and the certificate of calibration, stating the instrument has been calibrated using a process in compliance with ISO 17025 and is operating within the published specifications.

For more information on these options, visit [www.Keysight.com/find/calibration](http://www.Keysight.com/find/calibration).

SCPI Errors

-100 to -200 Command Errors

-200 to -299 Execution Errors

-300 to -399 SCPI Specified Device-Specific Errors

-400 to -800 Query and System Errors

100 to 230 VNA-specific Errors

See Also

Analyzer Error messages.

-100 to -200 Command Errors

A command error indicates that the test set's GPIB parser has detected an IEEE 488.2 syntax error. When one of these errors is generated, the command error bit in the event status register is set.

-100 std_command Command - This event bit (Bit 5) indicates a syntax error, or a semantic error, or a GET command was entered, see IEEE 488.2, 11.5.1.1.4.

-101 std_invalidChar Invalid character - Indicates a syntactic elements contains a character which is invalid for that type.

-102 std_syntax Syntax - Indicates that an unrecognized command or data type was encountered. For example, a string was received when the device does not accept strings.

-103 std_invalidSeparator Invalid separator - The parser was expecting a separator and encountered an illegal character. For example, the semicolon was omitted after a program message unit.

-104 std_wrongParamType Data type - The parser recognized a data element different than one allowed. For example, numeric or string data was expected but block data was encountered.

-105 std_GETNotAllowed GET not allowed - Indicates a Group Execute Trigger was received within a program message. Correct the program so that the GET does not occur within the program code.

<td>Expression - This error, as well as errors -171 through -179, are generated when parsing an expression data element. This particular error message is used if the device cannot detect a more specific error.</td>
</tr>
<tr>
<td>-171 std_invalidExpression</td>
<td>Invalid expression - Indicates the expression data element was invalid, see IEEE 488.2, 7.7.7.2. For example, unmatched parentheses or an illegal character.</td>
</tr>
<tr>
<td>-178 std_exprNotAllowed</td>
<td>Expression data not allowed - Indicates a legal expression data was encountered, but was not allowed by the device at this point in parsing.</td>
</tr>
</tbody>
</table>
-180 std_macro  Macro - This error, as well as error -181 through -189, are generated when defining a macro or execution a macro. This particular error message is used if the device cannot detect a more specific error.

-181 std_validOnlyInsideMacro  Invalid outside macro definition - Indicates that a macro parameter place holder was encountered outside of a macro definition.

-183 std_invalidWithinMacro  Invalid inside macro definition - Indicates that the program message unit sequence, sent with a *DDT or a *DMC command, is syntactically invalid, see IEEE 488.2, 10.7.6.3.

-184 std_macroParm  Macro parameter - Indicates that a command inside the macro definition had the wrong number or type of parameters.

-200 to -299 Execution Errors

These errors are generated when something occurs that is incorrect in the current state of the instrument. These errors may be generated by a user action from either the remote or the manual user interface

-200 std_execGen  Execution - This event bit (Bit 4) indicates a PROGRAM DATA element following a header was outside the legal input range or otherwise inconsistent with the device's capabilities, see IEEE 488.2, 11.5.1.1.5.

-201 std_invalidWhileInLocal  Invalid while in local

-202 std_settingsLost  Settings lost due to rtl

-203 std_commandProtected  Command protected - Indicates that a legal password-protected program command or query could not be executed because the command was disabled.

-210 std_trigger  Trigger

-211 std_triggerIgnored  Trigger ignored

-212 std_armIgnored  Arm ignored

-213 std_initIgnored  Init ignored

-214 std_triggerDeadlock  Trigger deadlock

-215 std_armDeadlock  Arm deadlock

-220 std_parm  Parameter - Indicates that a program data element related error occurred.

-221 std_settingsConflict  Settings conflict - Indicates that a legal program data element was parsed but could not be executed due to the current device state.
<table>

<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-222</td>
<td>std_dataOutOfRange: Data out of range - Indicates that a legal program data element was parsed but could not be executed because the interpreted value was outside the legal range defined by the devices.</td>
</tr>
<tr>
<td>-223</td>
<td>std_tooMuchData: Too much data - Indicates that a legal program data element of block, expression, or string type was received that contained more data than the device could handle due to memory or related device-specific requirements.</td>
</tr>
<tr>
<td>-224</td>
<td>std_illegalParmValue: Illegal parameter value - Indicates that the value selected was not part of the list of values given.</td>
</tr>
<tr>
<td>-225</td>
<td>std_noMemoryForOp: Out of memory - The device has insufficient memory to perform the requested operation.</td>
</tr>
<tr>
<td>-226</td>
<td>std_listLength: Lists not same length - Attempted to use LIST structure having individual LIST's of unequal lengths.</td>
</tr>
<tr>
<td>-230</td>
<td>std_dataCorruptOrStale: Data corrupt or stale - Indicates invalid data, a new reading started but not completed since the last access.</td>
</tr>
<tr>
<td>-231</td>
<td>std_dataQuestionable: Data questionable - Indicates that measurement accuracy is suspect.</td>
</tr>
<tr>
<td>-232</td>
<td>std_invalidFormat: Invalid format.</td>
</tr>
<tr>
<td>-233</td>
<td>std_invalidVersion: Invalid version - Indicates that a legal program data element was parsed but could not be executed because the version of the data is incorrect to the device. For example, a not supported file version, a not supported instrument version.</td>
</tr>
<tr>
<td>-240</td>
<td>std_hardware: Hardware - Indicates that a legal program command or query could not be executed because of a hardware problem in the device.</td>
</tr>
<tr>
<td>-241</td>
<td>std_hardwareMissing: Hardware missing - Indicates that a legal program command or query could not be executed because of missing device hardware. For example, an option was not installed.</td>
</tr>
<tr>
<td>-250</td>
<td>std_massStorage: Mass storage - Indicates that a mass storage error occurred. The device cannot detect the more specific errors described for errors -251 through -259.</td>
</tr>
<tr>
<td>-251</td>
<td>std_missingMassStorage: Missing mass storage - Indicates that a legal program command or query could not be executed because of missing mass storage.</td>

-293 std_nameAlreadyExists  Referenced name already exists
-294 std_incompatibleType   Incompatible type

-300 to -399 SCPI Specified Device-Specific Errors

A device-specific error indicates that the instrument has detected an error that occurred because some operations did not properly complete, possibly due to an abnormal hardware or firmware condition. For example, an attempt by the user to set an out of range value will generate a device specific error. When one of these errors is generated, the device specific error bit in the event status register is set.

-300 std_deviceSpecific     Device specific - This event bit (Bit 3) indicates that a device operation did not properly complete due to some condition, such as overrange see IEEE 488.2, 11.5.1.1.6.
-310 std_system             System
-311 std_memory             Memory - Indicates some physical fault in the devices memory, such as a parity error.
-312 std_PUDmemoryLost      PUD memory lost - Indicates protected user data saved by the *PUD command has been lost, see IEEE 488.2, 10.27.
-313 std_calMemoryLost      Calibration memory lost - Indicates that nonvolatile calibration data used by the *CAL? command has been lost, see IEEE 488.2, 10.2.
-314 std_savRclMemoryLost   Save/recall memory lost - Indicates that the nonvolatile data saved by the *SAV command has been lost, see IEEE 488.2, 10.33.
-315 std_configMemoryLost   Configuration memory lost - Indicates that nonvolatile configuration data saved by the device has been lost.
-320 std_storageFault       Storage fault - Indicates that the firmware detected a fault when using data storage. This is not an indication of physical damage or failure of any mass storage element.
-321 std_outOfMemory        Out of memory - An internal operation needed more memory than was available
-330 std_selfTestFailed     Self-test failed - Indicates a problem with the device that is not covered by a specific error message. The device may require service.
-340 std_calFailed Calibration failed - Indicates a problem during calibration of the device that is not covered by a specific error.
-350 std_queueOverflow Queue overflow - Indicates that there is no room in the queue and an error occurred but was not recorded. This code is entered into the queue in lieu of the code that caused the error.
-360 std_comm Communication - This is the generic communication error for devices that cannot detect the more specific errors described for error -361 through -363.
-361 std_parity Parity in program message - Parity bit not correct when data received for example, on a serial port.
-362 std_framing Framing in program message - A stop bit was not detected when data was received for example, on a serial port (for example, a baud rate mismatch).
-363 std_inputBufferOverrun Input buffer overrun - Software or hardware input buffer on serial port overflows with data caused by improper or nonexistent pacing.

A Query error is generated either when data in the instrument's GPIB output queue has been lost, or when an attempt is being made to read data from the output queue when no output is present or pending.

-400 std_queryGen Query - This event bit (Bit 2) indicates that an attempt to read data from the Output Queues when no output is present or pending, to data in the Output Queue has been lost see IEEE488.2, 11.5.1.1.7.
-410 std_interrupted Query INTERRUPTED - Indicates the test set has been interrupted by a new program message before it finishes sending a RESPONSE MESSAGE see IEEE 488.2, 6.3.2.3.
-420 std_terminated Query UNTERMINATED - Indicates an incomplete Query in the program see IEEE 488.2, 6.3.2.2.
-430 std_deadlocked Query DEADLOCKED - Indicates that the Input Buffer and Output Queue are full see IEEE 488.2, 6.3.1.7.
-440 std_responseNotAllowed Query UNTERMINATED after indefinite response - Indicates that a query was received in the same program message after a query requesting an indefinite response was executed see IEEE 488.2, 6.5.7.5.

-500 std_powerOn Power on
-600 std_userRequest User request
-700 std_requestControl Request control
-800 std_operationComplete Operation complete

Software Support

Each software license includes free software updates and support for the specific instrument application for the duration of your support subscription. A perpetual license includes software updates and support for the first year, after which support can be renewed annually for a fee. A subscription-based license includes software updates and support through the term of the license.

There are three dialogs that provide support information:

- My Software Support
- My Support ID
- Licensed Features

Access Software Support

Using Hardkey/SoftTab/Softkey

Using a mouse

1. Click Help.
2. Select Tech Support.

My Software Support

This dialog displays software-specific support information.

Refer to the Keysight PNA Series Firmware History support page to check the firmware version history specific to the date displayed in the Software Version Date column in the My Software Support dialog:
**Model Number** - Displays the model number of the feature.

**Description** - Displays a description of the feature.

**Support Expiration** - Displays the support expiration date.

**License Expiration** - Displays the license type.

**Contact Keysight** button - Opens the dialog showing contact information:

![Contact Keysight Dialog](image)

**My Support ID**

This dialog displays your support IDs used to register for software updates, services, and technical support. The support ID is typically the same as the host ID used to serve licenses. Your product configuration may have more than one support ID, each comprised of multiple fields of information.
Model Number - Displays the model number of the feature.

Description - Displays a description of the feature.

Support ID - Displays your support ID, which is typically the same as the host ID.

Copy icon - Copy the corresponding ID information to the clipboard.

Copy All to Clipboard... button - Copies all the contents of this dialog to the clipboard.

Licensed Features

This dialog displays a list of new features in the VNA firmware and corresponding license.

On start-up, the following dialog appears if the user has at least one feature with an expired support contract. In this case, the columns Current Support Contract and Enabled are hidden. ONLY the expired features/licenses are shown.
In the normal case, all licenses are shown and all columns are shown.

<table>

Redistribution of TightVNC is licensed under the General Public License version 2. Source code of TightVNC and a copy of the GPLv2 may be found in the directory of \opensource\TightVNC.

Portions of this software are distributed under one or more Open Source terms and are not warranted and supported by Keysight. This disclaimer does not affect any statutory rights that may exist in any country of distribution. The disclaimed Open Source software portions include the following software package(s): TightVNC. The text of the license for each software package is contained in a directory reflecting the name of the Open Source software that is found in the "\opensource" directory. The author and not Keysight grants a license to use and further distribute the Open Source software. Any license to use and further distribute the Open Source software is granted by the author(s) of such Open Source software in their Open Source license, not by Keysight in this license instrument. The author(s)’s license terms, if any, are found in text files and, if applicable, the source code of the separate Open Source software packages.

TO THE EXTENT PERMITTED BY LOCAL LAW:

Keysight provides the Open Source software listed above "as is" and any express or implied warranties, including, but not limited to any warranty of non-infringement, the implied warranties of merchantability, satisfactory quality, reasonable care and skill, and fitness for a particular purpose are expressly disclaimed; and

Keysight shall not be liable for any direct, indirect, incidental, special, exemplary, or consequential damages (including: procurement of substitute goods or services; loss of use, data, or profits; or business interruption) arising from the use of open source software, however caused and regardless of whether such claims are based upon contract, strict liability or tort (except gross negligence or willful misconduct of Keysight), or any other legal theory even if advised of the possibility of such damage and even if it has been ensured that such data can be reconstructed with reasonable expenditure from data material provided in machine-readable form.

Commercial Software License

MathWorks MATLAB Compiler Runtime v7.14
MathWorks MATLAB Compiler; Permission to use the MatLab MCR library is defined in a license agreement between MatLab and you, the Licensee. A copy of the license agreement may be found in “c:\Program Files (x86)\MATLAB\MATLAB Compiler Runtime” directory.
Diagnostic Tools, Utilities, and Adjustments

The following Tools, Utilities, and Adjustments are available to help you keep your VNA at peak performance.

**Diagnostic Tools**

- Operators Check
- System Verification
- Display Test

**Utilities**

- Receiver Display
- Restore ECAl Memory
- Speaker Volume
- Receiver Temperature

**Adjustments**

*Not all of the adjustments listed below are valid for every VNA model. Only the adjustments needed for each particular VNA will be listed.*

To access the service adjustments on the VNA, click **Utility**, then **System**, then **Service**, then **Adjustment Routines**...

**Standard and TDR Adjustments**

**Standard Adjustments**
Adjustments should be performed in the order listed (in green.)
All adjustments require that you be an administrator on this analyzer.
### TDR Adjustments

<table>
<thead>
<tr>
<th>Adjustment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10MHz Freq Adjustment</td>
<td>Adjusts frequency reference to exactly 10MHz.</td>
</tr>
<tr>
<td>EE Default Adjustment</td>
<td>Initializes or adjusts EEPROM values for several assemblies.</td>
</tr>
<tr>
<td>Source Adjustment</td>
<td>Adjusts source power level vs frequency.</td>
</tr>
<tr>
<td>Synthesizer DAC Adj.</td>
<td>Adj Synth for lowest phase noise.</td>
</tr>
<tr>
<td>IF Gain Adjustment</td>
<td>Adjusts Gain of IF Mux</td>
</tr>
<tr>
<td>Receiver Characterization</td>
<td>Adjusts receiver high level amplitude response.</td>
</tr>
<tr>
<td>Receiver Adjustment</td>
<td>Adjusts all receivers for flat frequency response.</td>
</tr>
<tr>
<td>LFE Receiver Adjustment</td>
<td>Adjusts LFE receivers for flat frequency response.</td>
</tr>
<tr>
<td>IF Response Adjustment</td>
<td>Adjusts IF Freq amplitude, phase, &amp; offsets.</td>
</tr>
<tr>
<td>Noise Adjustment</td>
<td>Adjusts noise IF gain and noise power flatness.</td>
</tr>
<tr>
<td>System Default Cal</td>
<td>Creates system cal for TDR and other uses.</td>
</tr>
</tbody>
</table>

Adjustments should be performed in the order listed (in green.)

All adjustments require that you be an administrator on this analyzer.
- 10 MHz Reference Frequency Adjustment
- EE Default Adjustment
- Synthesizer Bandwidth Adjustment
- Source Adjustment
- Synthesizer DAC Adj.
- IF Gain Adjustment
- Receiver Characterization
- Receiver Adjustment
- LFE Receiver Adjustment
- IF Response Adjustment
- **IF Response Adjustment** (applies ONLY to instruments with serial prefix 6021 and above with A.14.00.xx firmware and above.)

- Noise (Figure) Adjustment

- System Default Calibration

**mmWave System Adjustments**

When a Millimeter mode is detected, the following adjustments are displayed.

- LO Adjustment for mm Mode
- LFE Receiver Adj.
- IF Gain Adj for mm Mode
- Source and Receiver Adj.
- Receiver Characterization
- IF Response Adj. for mm Mode
The performance of the network analyzer is specified in two ways: system specifications, and instrument specifications. It is the end user’s responsibility to determine which set of specifications is applicable to their use of the analyzer.

A network analyzer measurement “system” includes the analyzer, calibration kit, test cables, and any necessary adapters. The system verification software in the analyzer is used to verify the system’s conformance to the “system” specifications. A “pass” result demonstrates that the analyzer, test cables, and adapters, perform correctly as a system. It DOES NOT demonstrate that any one component performs according to its individual specifications. A change to any part of this measurement system requires a re-verification of the system.

Instrument specifications specify the network analyzer’s uncorrected measurement port characteristics and its output and input behavior. The analyzer performance tests are used to verify the analyzer’s conformance to “instrument” specifications.

The system verification utility verifies the analyzer system specifications by automatically measuring the magnitude and phase for all four S-parameters for each verification device, and comparing the values against the following:

- Factory measured data from files on the verification disk
- Limit lines based on the measurement uncertainty

System Verification requires the use of a calibration kit and verification kit which has been certified within the past 12 months by Keysight. System Verification can NOT be used to perform this kit certification.

Operator's Check should also be performed to verify the basic operation of the analyzer.

- Equipment Used in the System Verification
- Precautions for Handling Airlines
- Flow Diagram of Procedure
- Procedure for System Verification
- If the System Fails the Verification Test
- Interpreting the Verification Results
**Notes**

- Although the performance for all S-parameters is measured, the S-parameter phase uncertainties are less important for verifying system performance. Therefore, the limit lines will not appear on the printouts.

- System Verification can NOT be run with a Multiport test set enabled. However, you can run a performance check as described in the Test Set User's Guide. See the N44xx User's Guide.

- The M9485A supports only ports 1 to 4. When the M9485A has any M9377As, system verification is not supported.

### Equipment Used in the System Verification

#### VNA Models with 3.5 mm test ports

**Cable Substitution**

The test port cables specified for the analyzer have been characterized for connector repeatability, magnitude and phase stability with flexing, return loss, insertion loss, and aging rate. Since test port cable performance is a significant contributor to the system performance, cables of lower performance will increase the uncertainty of your measurement. It is highly recommended that the test port cables be regularly tested.

If the system verification is performed with a non-Keysight cable, ensure that the cable meets or exceeds the operation of the specified cable. Refer to the cable User's Guide for specifications.

**Cable Flex Factor**

Flex Factor determines how much of the cable phase uncertainty to include in determining the limit lines.

- Set to 0% (zero) if the cables are held down in a fixture and are not allowed to move during the calibration and verification.
- Set to 100% if the cables are allowed to move a lot.

**Calibration Kit Substitution**

Non-Keysight calibration kits are not recommended nor supported.

**Precautions for Handling Airlines**

When you are using the airlines in the verification kit, observe the following practices to ensure good measurement techniques.

- Be very careful not to drop the airline's center or outer conductor. Damage will result if these devices are
dropped.

- Use proper Electro-Static Discharge (ESD) procedures.
- Clean your hands or wear gloves as skin oils will cause a change in electrical performance.

Flow Diagram of Procedure

The operational flow of the software is depicted by the flowchart shown below.
Procedure for System Verification

1. If you want printed test outputs, connect a printer to the analyzer. Let the analyzer warm up for at least 30 minutes.
2. Insert the verification kit USB memory into the analyzer USB port.

3. Press **System** > **Service** > **Verification** > **System Verification**. The System Verification window similar to this will be displayed.

**System Verification Dialog**

4. In the **Calibration Kit** box, select the calibration kit or ECal module that is being used. The corresponding verification kit to use appears in the **Verification Kit** box.

5. Under **Printer Output** click on any of the following options.

   - **Print Tabular Data**: Prints the verification data in tabular form which includes measured data and uncertainty limits. Refer to a tabular data example, later in this topic.

   - **Print Graphs**: Prints the verification data in graphical form. The graphic form includes the measured data trace, factory supplied data trace and uncertainty limits. Refer to a plot data example, later in this topic.

   - **File Tabular Data**: Writes the verification data in tabular form to a text file in the D:\ directory.

   - **File Graphs**: Saves a screen image in .PNG format in the D:\ directory.

**Note**: If you want printed output, it is assumed you have already installed the Windows driver for your particular printer, and have tested that you can print to the printer from the network analyzer. This software is designed to print to whichever printer is currently set as the Default printer (see Printers in the Windows Control Panel).
6. To modify the number of ports to be verified, to change the number of devices to measure, or to use a previously stored verification calibration, click on the Configure tab and make the desired selections.
   - For the system verification to be truly adequate, the software must measure all devices in the kit with a recent calibration applied. Removing and reattaching any test port cables or adapters invalidates all previous calibrations.

7. Click Run.

8. Follow the instructions on the analyzer for performing the system verification, inserting the verification devices as prompted.

**Note for 3 Port analyzer:**
The System Verification Procedure is repeated three times. The first time, **Ports 1 and 2** are measured as a pair; then **Ports 1 and 3** are measured; and lastly, **Ports 2 and 3** are measured.

**Note for 4 Port analyzer:**
The System Verification Procedure is repeated two times. The first time, **Ports 1 and 2** are measured as a pair, then **Ports 3 and 4** are measured.

---

**Step-by-Step Process Description**

1. Depending upon the selected choice in the Calibration submenu of the Configure menu, the user is either prompted to recall a previous calibrated instrument state, or is guided through a full 2-port calibration using the selected calibration kit. For ECal, the ECal module is connected just once; a standby message is posted while the software is performing the calibration.

2. The user is prompted to connect the first verification device.

3. The software reads the factory measured data for that device and uncertainty values for that data (CITIfiles) from the floppy disk supplied with the verification kit.

4. The software sends the factory measured data, calibration kit and instrument state information to the uncertainty calculator DLL, which generates uncertainty values specific to the analyzer.

5. The analyzer first sets up for magnitude measurements of all four S-parameters, each parameter in a separate window (lin mag for $S_{11}$ and $S_{22}$, log mag for $S_{21}$ and $S_{12}$). Each of the factory measured S-parameters are fed to the appropriate window as a memory trace. Limit line offsets are calculated as the sum of the factory measured data uncertainties and analyzer uncertainties reported by the DLL. Upper and lower limits are displayed (factory measured data + uncertainty sum, factory measured data - uncertainty sum). The analyzer takes a sweep, limit test is turned on and PASS/FAIL status is reported in each of the four windows.

6. The user clicks a button when ready to view phase measurements. The four windows get updated for phase format, phase memory traces, phase limits and PASS/FAIL result.

7. If the limit test of any of the four S-parameters (magnitude or phase) indicates a FAIL status, the software
suggests troubleshooting tips and asks if the user would like to repeat measurement of that device or proceed to the next device. If proceeding to the next device, the factory measured data and uncertainties for the next device are read from floppy, the uncertainty DLL gets called with this next set of factory measured data, and the four measurement windows get updated for magnitude measurement of the next device.

8. The software follows this same process until all selected devices have been measured, at which point a summary window is displayed containing the set of PASS/FAIL results for all four parameters of each device.

**If the System Fails the Verification Test**

**IMPORTANT:** Inspect all connections. Do not remove the cable from the analyzer test port. This will invalidate the calibration that you have done earlier.

1. Repeat this verification test. Make good connections with correct torque specifications for each verification device.

2. Disconnect, clean and reconnect the device that failed the verification test. Then measure the device again.

3. If the analyzer still fails the test, check the measurement calibration by viewing the error terms as described in "Front Panel Access to Error Terms" on page 4-7 of the Service Guide.

4. Refer to the graphic below, for additional troubleshooting steps.

**Verification Fails Flowchart**
Interpreting the Verification Results

The graphic below shows an example of typical verification results with **Tabular Data** selected in the **Printer Output** area of the **System Verification** window. A graphic later in this topic shows an example of typical verification results with **Measurement Plots** selected in the **Printer Output** area of the **System Verification** windows. These printouts include a comparison of the data from your measurement results with the traceable data and corresponding uncertainty specifications. Use these printouts to determine whether your measured data falls within the total uncertainty limits at all frequencies.

The tabular data consists of:

- Frequency of the data points (in MHz).
- Lower limit line as defined by the total system uncertainty specification.
- Results of the measurement.
- Upper limit line as defined by the total system uncertainty specification.
- Test status (PASS or FAIL) of that measurement point.
The printed graphical results show:

- Upper limit points as defined by the total system uncertainty specifications.
- Lower limit points as defined by the total system uncertainty specifications.
- Data measured at the factory.
- Results of measurements.
- Measurement parameter names and formats (Lin Mag or Log Mag).
- Serial number of device (00810).
- Device being measured (Sys Ver 20 dB attenuator).
Tip: Use Move App to Back to cause the VNA application to move behind this application on the screen.

Overview

The Operator's Check should be performed when you first receive your VNA, and any time you wish to have confidence that the VNA is working properly.

Notes

- The Operator's Check does not verify performance to specifications. To verify VNA performance to specifications, run System Verification.
- Allow the VNA to warm up for 90 minutes before considering a failed test to be valid.
- The Operator's Check can NOT be run with a Multiport test set enabled. However, you can run a performance check as described in the Test Set User's Guide. See the N44xx User's Guide.

The Pass/Fail criteria used in the Operator's Check identifies obvious failures in the following portions of the VNA hardware:

- Repeatability of the RF switch in the test set
- Attenuation ranges of the test port attenuators (if installed).
- Calibration of the receivers
- Frequency response of the receivers
- Phase lock and leveling
- Noise floor and trace noise
How to Run the Operator's Check

Using Hardkey/SoftTab/Softkey

1. Press **System** > **Service** > **Operator's Check**.

1. Follow the instructions to proceed with the test.

Standard Dialog

The following dialog is displayed for standard VNAs.

Wideband Millimeter Wave Dialog

The following dialog is displayed for wideband millimeter wave systems.
This dialog box will look slightly different, depending on VNA model number and installed options. Some of the tests are not run if the appropriate option is not installed.

To learn about how each test is performed, click one of the tests on the right of the dialog. For example, the following information dialog is launched when **Leveling** is clicked:
Operators Check dialog box help

Note: It is normal for a momentary unleveled condition to appear during portions of the Operators Check.

Configure

Prompt for attachment of Short / Open  If you do not have enough shorts or opens for all test ports, you will be prompted to move the standard to the next test port. Connect either a short or open to port 1, then click Begin.

Shorts / Opens are attached to all ports  Connect either a short or open for each test port, then click Begin. All ports are tested without interruption. You can mix shorts and opens on the test ports.

VNA  Shows information about the VNA that is being tested.

Legend  Shows the status icons used in the Operator's Check and their meaning. Pending Pass means that a portion of the testing has been completed successfully.

Results  Shows the current status of each test. Click on the test name to learn how that test is performed. This may help in troubleshooting failed tests. If any tests Fail, refer to Chapter 3 of the VNA service guide.

Begin  Starts the Operator's Check.

View Results  Shows all results in text format. Failed items are preceded by ====》》》.

This text file can be printed or saved with a unique file name to compare results with previous or subsequent testing.

Exit  Ends the program and closes the window.
**Display Test**

The VNA screen should be bright with all annotations and text readable. The display test allows you to check for non-functioning pixels and other problems.

**Note** If the display is dim or dark, refer to “Troubleshooting LCD Display Problems” in the VNA Service Guide.

**What Is a Damaged Pixel?**

A pixel is a picture element that combines to create the image on the display. They are about the size of a small pin point. Damaged pixels can be either “stuck on” or “dark.”

- Stuck on pixel - red, green, or blue; always displayed regardless of the display setting. It will be visible on a dark background.
- Dark pixel - always dark; displayed against a background of its own color.

**How to Run the Display Test**

Press **System > Service > Diagnostics**, and then click **Display Test...**

A multi-color screen is displayed. Be prepared to look for the symptoms described below. Click the Start Test button. To continue to the next test, click the moving Next Test button. The button moves to allow you to see all of the display. After the test is completed, the display defaults to the network analyzer screen.

**How to Identify a Faulty Display**

One or more of the following indicate a bad display:

- Complete row or column of “stuck on” or “dark” pixels
- More than six “stuck on” pixels (but not more than three green)
- More than twelve “dark” pixels (but not more than seven of the same color)
- Two or more consecutive “stuck on” pixels or three or more consecutive “dark” pixels (but no more than one set of two consecutive dark pixels)
- “Stuck on or “dark” pixels less than 6.5 mm apart (excluding consecutive pixels)

If any of these symptoms occur, your display is considered faulty. See the Service Guide for your VNA.
model.
10 MHz Reference Frequency Adjustment

This routine adjusts the analyzer's internal time-base to exactly 10 MHz by changing a DAC value. This DAC value is stored in the analyzer's non-volatile memory. This routine should only be necessary in the following situations:

- The frequency reference assembly is replaced.
- The 10 MHz reference has drifted significantly from the factory adjusted value.

**WARNING:** The range of this adjustment is only about 20 Hz. It is highly recommended that a very accurate frequency standard be used to measure this 10 MHz signal.

**Frequency Counter Compatibility**

This procedure uses SCPI commands (over GPIB) to communicate with the frequency counter. It should work with the Keysight R5313xA, 5315xA, 53181A series of counters as well as the older 5350 series.

If no compatible counters are available, select the "Manual" mode of operation.

**Procedures**

**Note:** You must be logged onto the VNA as an Administrator to perform an adjustment. [Learn more.]

Click **Utility**, then **System**, then **Service**, then **Adjustment Routines**...

At the Adjustments selection, click **10 MHz Frequency Adjustment**

**Procedure for GPIB Counters Only**

1. Connect the analyzer rear panel 10 MHz Reference output to the frequency counter.
2. Connect a GPIB cable from the analyzer to the counter. Make sure no other controllers are active on the same connection.
3. If applicable, connect the house frequency standard to the counter reference input.
4. Set the counter GPIB address to 03. Ensure that the counter is the only device at this address.
5. On the VNA, press **System** > **Service** > **Adjustment Routines**..., then **10 MHz Freq. Adjust**.
6. Click **Begin Adj.** The application adjusts the internal reference for minimal error and stores the results.

7. Click **Read Freq** to trigger another reading of the 10 MHz signal.

8. Read the current DAC value stored in the analyzer's non-volatile memory (value = 0 - 4095).

9. When the status area indicates the adjustment is complete, click **Exit**.

**Procedure for Non-GPIB Counters**

1. Connect the counter input to the rear panel 10 MHz Reference Output.

2. Set the counter to at least 1 Hz resolution.

3. If applicable, connect the house-frequency standard to the counter reference input.

4. In the analyzer **System > Service > Adjustment Routines...**, then click **10 MHz Freq. Adjust**

5. Under **Frequency Counter**, select **Manual**.

   - Adjust the slider bar **arrows** until the frequency counter reads 10.0 MHz at your desired level of accuracy.
   - Click **Exit** to save the results.

**Data Storage**

- The correction data is stored in the EEPROM on the 10MHz Ref board assembly.

**Note:** If the counter is misreading the frequency, it may be necessary to attenuate the input, or set the input impedance to 50 ohms, or both.
Source Adjustment

Source Adjustment is a **SERVICE** Routine which should be performed when a component in the source chain is replaced, or when the VNA fails an annual calibration. It adjusts the VNA source power for flatness across its full frequency range.

This topic does **NOT** discuss **Source Power Calibration**, which calibrates a VNA source over the current measurement range.

Required Equipment

**Note:** The power sensor depends on the VNA frequency range. Depending on the VNA model, two power sensors may be required to test the full frequency range. The VNA front panel connector type will determine the cable used and if an adapter is required with the power sensor(s).

See list of supported power meters and sensors.

See VNA Accessories

Procedure

**Note:** You must be logged onto the VNA as an Administrator to perform an adjustment. [Learn more.]

1. Refer to your power meter documentation to ensure the proper calibration factors for the power sensor have been entered into the table on the power meter.

2. Connect a GPIB cable between the power meter and network analyzer (use the System Controller GPIB port if applicable.)

3. Ensure the power sensor(s) are connected to the power meter.

4. Click **Utility**, then **System**, then **Service**, then **Adjustment Routines**...

5. At the Adjustments selection, click **Source Adjustment**

6. There are 3 different version of the Source Calibration software; all are slightly different. All have a button that is labeled "Calibrate" or "Adjust". This is the button that will begin the calibration process. Some versions will also have a button labeled "Verify" that will test the source calibration without making any changes. Other selections are for factory personnel use only.

7. Once begun, you must enter the power meter and sensor information. The software will verify the power meter and sensor. You are then prompted to connect the sensor(s) and cable as needed.

**Connecting sensors to the VNA**
Additional Information

All ports are tested on all VNAs. Source calibration takes approximately 10 to 45 minutes to complete depending on the frequency range and model number of the VNA.

Troubleshooting

In the event there is a problem with Source Adjustment, please refer to the "Troubleshooting" chapter in the VNA Service Guide.

Data Storage

- The correction data is stored in the flash memory on the Test Set Mother Board.
IF Gain Adjustment

This adjustment sets the IF attenuator/gain stages to present a relatively consistent level to the ADC versus frequency for a given amount of signal. This maximizes the dynamic range of the instrument by preventing any IF compression at higher levels. The adjustment range is about 18dB with one adjustment value per band per input: R1, R2, R3, R4, A, B, C, and D (if applicable.)

The program first finds the peak of each band’s frequency response with a fixed input level. It then re-measures those peaks with a power meter. From this information, it determines the optimum gain or attenuation needed to keep all bands as similar as possible for any given frequency.

When to perform

IF Gain Adjustment should be performed when any of the following occur:

- An assembly in the reference receiver path (R1,R2) is replaced.
- The Test Set Motherboard is replaced
- The IF Mux assembly or SPAM assembly is replaced

Required Equipment

- Power Meter and Sensor(s) - These must cover the full frequency range of the VNA.
- GPIB cable, LAN, or USB cable depending upon the type of Power Meter/Sensor being used.
- Adapters as needed

Procedure

Note: You must be logged onto the VNA as an Administrator to perform an adjustment. Learn more.

Click Utility, then System, then Service, then Adjustment Routines...

At the Adjustments selection, click IF Gain Adjustment.
Note: Connect the Power Meter/Sensor to the VNA USB, GPIB, or LAN input depending on the type of Power Meter/Sensor being used. The program will prompt you where and when to attach the RF input for the Power Sensor(s).

Ensure the Reference Channel paths are properly configured and the connections are properly torqued.

1. Click **Begin**

2. Follow the instructions displayed in the program.

The adjustment takes about 5 minutes to complete for a 26.5 GHz VNA. Higher frequency units may take longer.

The Default menu selection (under the advanced menu) is for factory personnel only. This will preset all values to default levels for trouble shooting purposes only. If this is selected, a full IF gain adjustment will need to be performed.

**Data Storage**
- The correction data is stored in the flash memory on the Test Set Mother Board.
Receiver Adjustment

This program adjusts the network analyzer receivers for a flat response across its full frequency range. This adjustment is for service only; not for measurement calibration.

Required Equipment

See list of supported power meters and sensors.

See VNA Accessories

Notes

- The power sensor depends on the VNA frequency range. Depending on the VNA model, two power sensors may be required to test the full frequency range. The VNA front panel connector type will determine the cable used and if an adapter is required with the power sensor(s).

- In this adjustment, a power sensor with a specified lower frequency limit of 50 MHz may be used on all instrument that have a lower frequency limit of 10 MHz. Any added uncertainty is negligible.

- If using an older style sensor (without built-in correction factors), refer to your power meter documentation to ensure the proper calibration factors for the power sensor have been entered into a table on the power meter.

- You must be logged onto the VNA as an Administrator to perform an adjustment. Learn more.

Procedure

1. Click Utility, then System, then Service, then Adjustment Routines...

2. At the Adjustments selection, click Receiver Adjustment

3. Connect a GPIB cable between the power meter and network analyzer.

4. Ensure the power sensor(s) are connected to the power meter.

5. The software presents you with two choices:

   a. Click Inspect Flatness to observe flatness of receiver response versus frequency. Although there is no
explicit specification for receiver flatness, Receiver Calibration should improve Transmission and Reflection Tracking error terms which are specified.

b. Click **Calibrate** to begin the receiver calibration process. The software prompts you to connect the sensor(s), cable and adapter as needed (see the following graphics).

**Connecting sensor(s) to the VNA**

**Connecting adapter and cable between sensor and VNA**

**Through connection using the specified cable**
**Additional Information**

- Receiver Adjustment tests all VNA receivers, taking approximately 15 and 45 minutes. Length is dependent on frequency range and number of ports.

- Upon completion of the Receiver Adjustment, a transmission measurement of a good quality cable should appear to be smooth, with slightly increasing loss versus frequency. A reflection measurement of a short or open should appear to be a flat line across the entire frequency range with only a dB or two of variation/ripple. If instead, you see variations of 10-40dB, then the VNA may have a mixer problem. Typically, this means the uncorrected low end frequency phase relative to other receivers is different. This causes the correction algorithm to "blow up" and provide wildly incorrect data. This is almost always a hardware problem and typically one or more receivers must be replaced. The adjustment procedure has a quick test for this and it will show a warning message if excess phase shift is detected, however this test is not definitive and may not always catch every problem.

**Troubleshooting**

In the event there is a problem with Receiver Adjustment, please refer to the "Troubleshooting" chapter in your VNA Service Guide.

**Data Storage**

- The correction data is stored in the flash memory on the Test Set Mother Board.
The Receiver Display as a Troubleshooting Tool

The Receiver Display is a Troubleshooting Tool. It enables the analyzer to isolate faulty functional groups within its own Measurement System. Traces for each Receiver are Displayed in individual windows. Identifying discrepancies of the traces in these windows can help isolate the faulty assembly.

For a thorough description of Receiver Display and the troubleshooting steps see the Service Guide for your VNA. You can download the Service Guide from our website: http://na.support.keysight.com/pna/ or http://na.support.keysight.com/pxi/

How to Start the Receiver Display

**Using Hardkey/SoftTab/Softkey**

1. Press **System > Service > Diagnostics > Receiver Display...**

**Using a mouse**

1. Click **Utility**
2. Select **System**
3. Select **Service**
4. Select **Diagnostics**
5. Select **Receiver Display...**
Mechanical Counter

This feature keeps track of mechanical attenuator and switch changes. The firmware increments counters each time commands to change the attenuator or switch settings are sent. The dialog reads back the counters and allows a technician to reset the counters if the hardware components are replaced. This feature exists on all PNAs running firmware A.13.60 and above. There are no user SCPI commands to read these counter values remotely.

- To read/reset counters, press **System > Service > Diagnostics > Mechanical Counter...** The Mechanical Cycle Counter dialog is displayed:

![Mechanical Cycle Counter Dialog](image)

- Select the device to reset by clicking on its radio button located on the left side of the device name then click on the **Modify** button. The **Model and Serial Entry** dialog is displayed:
Follow the instructions in the dialog.

- Enter as much data as can be found for the new assembly and enter the count in the Enter Desired Count numeric field.
IF Path Configuration Settings

This dialog is used to set many IF receiver settings for models.

In this topic:

- VNA-X and N522xB IF Frequencies
- How to Start the IF Path Configuration dialog
- IF (Receiver) Path Configuration dialog box
- Expanded Block Diagram and Descriptions
- IF Path Configuration using COM and SCPI

Other IF Access Topics

Auto IF Frequencies

Wideband/Normal IF path:

Note: For the following discussion, RF = Receiver Frequency

With DSP Version 4:

- RF < 53 MHz: IF = 2.535211 MHz  \([3 \times (60e6 / 71)]\)
- RF >= 53 MHz: IF = 7.605634 MHz  \([9 \times (60e6 / 71)]\)

With DSP Version 5, the IF frequency is dependent on the RF AND the current IFBW setting:

- All RF; IF Bandwidth >= 1MHz: (All Models)
<table>
<thead>
<tr>
<th>IFBW Setting</th>
<th>IF Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 MHz</td>
<td>7.692 MHz</td>
</tr>
<tr>
<td>1.5 MHz</td>
<td>7.368 MHz</td>
</tr>
<tr>
<td>2 MHz</td>
<td>8.450 MHz</td>
</tr>
<tr>
<td>3 MHz</td>
<td>8.163 MHz</td>
</tr>
<tr>
<td>5 MHz</td>
<td>6.897 MHz</td>
</tr>
<tr>

<tr>
<td>10 MHz</td>
<td>15.38 MHz</td>
</tr>
<tr>
<td>15 MHz</td>
<td>22.22 MHZ</td>
</tr>
</tbody>
</table>

- IF Bandwidth <= 600 kHz:
  - RF >= 53 MHz; All models: IF = 7.438017 MHz \([(9 \times (100e6 / 121)]\]
  - RF <= 53 MHz; PNA-X models: IF = 2.479339 MHz \([(3 \times (100e6 / 121)]\]
  - RF <= 53 MHz; N522xB models: IF = 826.446 kHz \([1 \times (100e6 / 121)]\]

**Narrowband IF path:**

- IF = 10.70 MHz
- Bandwidth = 30 kHz

**Note:** The IFBW is limited to 600 kHz when performing Swept IMD measurements even if the **Wide IF path** is selected.

**Manually change the IF frequency**

**The IF frequency** can be changed to any value between +14.9999 MHz and -14.9999 MHz using **SENS:IF:FREQ** or **IFFrequency** commands.

- With DSP Version 4 - 34 and above, min and max IF frequencies up to +/- 20.1 MHz are available.
- With DSP Version 5, min and max IF frequencies up to +/- 38 MHz are available.
Performance is degraded drastically above +/- 14.9999 MHz.

Learn about DSP Version

How to start the IF Path Configuration dialog

Using **Hardkey/SoftTab/Softkey**

1. Press **Setup > Internal Hardware > IF Path Config...**

Using a mouse

1. Click **Instrument**
2. Select **Setup**
3. Select **Internal Hardware**
4. Select **IF Config...**

**Programming Commands**

**IF (Receiver) Path Configuration** dialog box help

![Diagram of IF Path Configuration](image)

The IF path, represented in the block diagram at the top of the dialog, is duplicated for each of the receivers (A, B, C, D, R1, R2, R3, R4). In addition, each path can be configured differently for each channel.

Element - Indicates an element in the expanded block diagram.

**IF Input** (1) - Available on the PNA-X and N522xB with Opt 020. Internal input is a test port or
reference receiver input. External Input is through the PNA-X and N522xB rear-panel connectors.

**IF Attenuator** (3) - Specify IF attenuation for the narrowband path of the selected receiver.

**IF Filter** (2) - Select Wideband or Narrowband (includes the ability to pulse gates).

**IF Gain** (10) - Set to **Auto** by default, the following are reasons to change the IF Gain:

- For **millimeter systems** that do NOT use the external millimeter test set, the millimeter head output IFs are routed directly to the RF receivers. You may want to change the IF gain to improve the noise figure of the receivers.

- External couplers are often used for high-power test setups. The VNA automatically adjusts the IF Gain depending on the frequency of operation in order to correct for several aspects of the hardware, including the large coupled-arm roll off at low frequencies (below 700MHz). If you replace the internal coupler with one having a different low-frequency roll off, then you may also want to change the IF gain to avoid overdriving the receiver.

- When using the rear panel direct IF inputs, the gain is set low when in standard operation and very high when in **millimeter mode**. You may want to control the gain of the direct IF inputs to improve noise figure or to avoid overdriving the receivers.

**ADC Filter** (5) - Select **Auto**, **Narrow** (9 MHz or 11 MHz), or **Wide** (16 MHz or 38 MHz) filter. Learn more.

**Couple all IF paths** - Check to make the same setting for all receivers.

Expanded Block Diagram (IF / Pulse Generators / DSP)
Blue boxes are configurable elements. Click a blue box, or scroll down, to see how to make settings using SCPI and COM commands.

**Receiver / IF Path (top block)**

Scroll up for descriptions of the Receiver / IF Paths blocks. Most of these elements can be set from the front-panel User Interface (UI).

**ADC:** (Analog to Digital Converter) This block, responsible for quantifying receiver measurements, is triggered when BOTH the Meas Trig line AND P0 pulse generator line are TRUE. In addition, the Meas Trig signal MUST be TRUE before or at the same time as the P0 signal.

**Meas Trig Signal**

- When VNA Trigger source is set to **Internal**, the Meas Trig line is ALWAYS TRUE. Internal trigger source is the best setting for making Pulse measurements. This means that the P0 line determines when pulse measurements are made.
- When VNA Trigger source is set to **External**, the Meas Trig line can be configured from the Meas Trig (External) dialog.

**P0 (Trig) Signal** - See below.

**Pulse Generators (middle block in above diagram)**
See how to make these settings remotely

**Switch 6:** Represents **Internal** or **External** triggering for the pulse generator. This setting, and the External Trigger Pulse settings, are made on the Trigger dialog, **Pulse Trigger tab.**

On the Integrated Pulse App, **Pulse Setup dialog,** when Pulse Trigger source is set to External, then External is selected automatically in the Pulse Gen dialog.

- **Internal** - The pulse generator is internally triggered and puts out a periodic pulse train with a period defined by the pulse generator settings.

- **External** - The pulse period is ignored, and the pulse generator puts out one set of pulses (P0-P4) per external trigger. All five pulse outputs have unique delay and pulse width settings.

  External trigger input is on the **Pulse I/O connector** pin 7 (PulseSyncIn). The PulseSyncIn line provides a trigger signal into the Pulse Generators. If a level trigger is still valid when the first set of pulses is finished, another set will be generated. Only one set of pulses is emitted when edge triggering is used.

  The External pulse input polarity (positive or negative) and type (edge or level) is configurable only with DSP version: 4.0 FPGA: 34 or higher. Learn more. Otherwise, the pulse generators respond only to positive, level input trigger signals.

**P0:** When P0 is enabled, it is hardwired to trigger the data acquisition ADCs. See ADC (above).

- If the data acquisition system is not ready (Meas Trig = NOT TRIGGERED), the P0 trigger is ignored.

- If the pulse generator is internally triggered, then the data acquisition system receives periodic triggers.

- If the pulse generator is externally triggered, then the data acquisition system receives a trigger each time the pulse generator is triggered.

Data acquisition is synchronized to the pulse generator **ONLY** when P0 is enabled. This is equivalent to enabling **Synchronize ADCs using pulse trigger** on the Pulse Generators Setup dialog. Data acquisition begins on the rising edge of P0. The width of P0 does NOT directly matter as data acquisition does not stop when P0 goes false. The following describes how the P0 generator triggers data acquisition:

- **Step mode sweeps** of any sweep type: By default, each P0 rising edge triggers a single data point. When **point averaging** is on, all of the measurements (subpoints) that are required to average each point are made with a single trigger. To individually trigger the acquisition of each subpoint, send the subPointTrigger (SCPI
or COM) command.

- **CW sweeps**: Each trigger initiates acquisition for the entire sweep. This is currently used for wideband pulse profiling.

**P1 thru P4** These four pulse generator outputs are hardwired to rear panel outputs on the Pulse I/O connector (pins 10 - 13). They are also routed to two switches (#4 and #7 on the above diagram) along with the following three lines:

  - **Rear Panel**  External pulse generator input from Pulse I/O connector pin 8 (RFPulseModIn).
  
  - **OFF**  Pulse is constantly in LOW state causing gate and source to be OFF.
  
  - **ON**  Pulse is constantly in HIGH state causing gate and source to be ON.

**Switch 7** Pulse Modulation - 1 of 7 lines to each of the sources. **Important**: When internally modulating the sources, source leveling must be set to Open-loop.

**Rear-panel Outputs**: Pulse I/O connector (pins 10 - 13) hardwired.

**Source1 and Source2 pulse modulators**: (#8 and #9 on the above diagram)

**DSP (bottom block)**

  - Filters the ADC (digital) output from top block and outputs data to the VNA display.

  - See SCPI and COM commands to control DSP settings.

This feature, when used with the N526xA test sets and external mmWave Modules, extends the frequency coverage of your VNA. The N5251A broadband system is also configured using the Millimeter Module Configuration dialog.

In this topic:

- Features and Limitations
- How to Configure Millimeter Modules
- Mixer Mode
- Spectrum Analyzer mmWave Measurements
- mmWave Module Power Level Control
- Using Cal All Wizard for Supported mmWave Measurement Classes

See Also

- N5261A / N5262A User Manual (Requires internet connection)
- N5251A Installation Guide (Requires internet connection)
- Millimeter-Wave Network Analyzers Technical Overview (Requires internet connection)
- Direct Connect: mmWave Measurements with No Test Set
- Download a macro for Configuring Frequency Extenders (Requires internet connection)

Other IF Access Topics

Note: In the VNA user interface and in this help file, the N526xA Millimeter Head Controller is referred to as a test set. The test head modules are referred to as mmWave modules.

CAUTION: Turn OFF test set power before connecting or disconnecting the DC cable to the mmWave modules.

Features
Controls N5261A and N5262A Test Sets.

Compatible with iTMSA (True Mode Stimulus).

Several methods available to provide Leveled power to the DUT Input

Compatible with Integrated Pulse Application

The following Applications are supported:

- SMC mixer measurements.
- IMSpectrum and IMSpectrum for Converters
- Spectrum Analyzer

The following configurations are supported:

- PNA-X or N522xA with options Opt 020 works with N5261A and N5262A Test Sets.
- When using the N5262A test set, a 2-port PNA-X or N522xB requires Opt S93551A/B.
- Broadband - single sweep from 10 MHz to 110 GHz.
- Banded - frequency coverage divided into bands.

Limitations

- **Power Settings** Your mmWave modules may have a variable attenuator on them. When used with an N5261A or N5262A, after performing a Source Power Cal, then the VNA power settings may be used to control the power into the DUT. See Leveled Power Capabilities.

- To protect your mmWave modules from damage, the settings on the Millimeter Module Configuration dialog can ONLY be changed manually. They can NOT be reset or changed by performing a Preset, by recalling an Instrument State, or from a remote program.

- ONLY the Applications listed above are supported.

Broadband and Banded mmWave Measurements

Broadband refers to mmWave configurations with a frequency range of 10 MHz to 110 GHz. This configuration spans the entire frequency range in a single sweep.

Banded refers to any configuration that is not a broadband configuration and is waveguide based.
Frequency extenders cover frequency ranges from 50 GHz to 1.1 THz. The supported solutions can be configured for different frequency bands with or without a test set controller depending on the measurements required and the frequency extenders being used.

The following table shows the waveguide designation equivalents.

**PNA-X Notes**

- The PNA-X or N522xB rear panel IF Inputs use 5 SMA connectors. Previous VNA models use BNC connectors. Adapters may be required.

- Frequency Offset and SMC Measurements are supported when using mmWave modules. Learn more.

- Beginning with A.10.45, Spectrum Analyzer Measurements are supported when using mmWave modules. Learn more.

**How to Configure Millimeter-Wave Modules**

**Using a mouse**

1. Click **Instrument**
2. Select **Setup**
3. Select **External Hardware**
4. Select **Millimeter Config...**
**Note:** To protect your mmWave modules from damage, settings on this dialog can ONLY be changed manually or with a remote program. They can NOT be reset or changed by performing a Preset, or by recalling an Instrument State.

**Available Configurations** Lists the Standard VNA configuration and other configurations that you have created.

- Click **New** for first-time use.
- For the N5251A, select **Broadband 10MHz - 110GHz**.
- For banded, define a frequency band.
- Select **Standard PNA** to exit the Millimeter Module Configuration dialog.

**Name** Shows the currently selected configuration. Edit this field to change the configuration name. Type a unique name using only alphanumeric characters and underscore.

**New** Click to create a new Millimeter Module configuration. A name is automatically selected. Edit the Selected Configuration field to change the configuration name.

**Remove** Deletes a Millimeter Module Configuration.
**Test Set Properties**

**Test Set**  Select a test set to use in the current configuration. The firmware does NOT check to ensure that the selected test set is connected.

**Mixer Mode**  Check to allow mixer testing using SMC. Learn more.

**Route VNA RF to rear panel "SW SRC OUT"**  Available ONLY on PNA-X with option 224 or 423 AND when using N5261A and N5262A test sets.

When checked, Port 1 source is switched to J11 and Port 3 source is switched to J8 on the VNA rear panel. Use this configuration to quickly switch the RF Output back to the VNA front panel.

**Enable Test Set RF ALC**  Available for N5261A and N5262A ONLY. When checked, power is automatically leveled at the mmWave module RF input when using the standard cables and making non-pulsed measurements. Clear this box to use non-standard cables or when making pulse measurements. When cleared, the following fields become available:

- **Max Power Limit**  The maximum mmWave module RF input is limited to this value when Test Set RF ALC is OFF. When you exit this dialog box using OK, set the power out of the VNA using the Power and Attenuator dialog.
- **Offset**  Sets the loss of the cables. The mmWave module RF input is adjusted by this amount. Positive offset increases the power.
- **Slope**  Helps compensate for cable and test fixture power losses at increased frequency. The mmWave module RF input power increases as the sweep frequency increases in dB/GHz. The slope is defined relative to the mmWave module RF input frequency. The slope starts at 0Hz and a positive slope will increase the power level. Range is +/- 2 dB/GHz.

**Note:** Changing any of the source controls after a calibration will cause the source power cal to be turned off. A source power cal will need to be performed again with the new settings.

**Frequency Settings**

- **Multiplier RF IN**  RF Frequency Range (displayed in grey fields) multiplied by this value = test port frequency range.
- **Multiplier LO IN**  LO Frequency Range (displayed in grey field) multiplied by this value equals the test port frequency. The IF frequency is:
  - 'C' Models = 8.333 MHz
  - PNA-X models = 7.605 MHz
**Test Port Frequency**  Set the Start and Stop frequencies of the selected configuration at the test ports. This becomes the displayed Start and Stop frequency of the VNA.

**Important Notes**

- To set Test Port Frequency, first set the appropriate **Multiplier** values that are specified in your mmWave module documentation.

- Ensure that the RF and LO Frequencies (highlighted below) are within the frequency range of the sources. The VNA offers no warning if they are NOT.

<table>
<thead>
<tr>
<th>Multiplier RF IN:</th>
<th>Start Frequency</th>
<th>Stop Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>12.5000000000 GHz</td>
<td>18.3333333333 GHz</td>
</tr>
<tr>
<td>Multiplier LO IN:</td>
<td>9.3750000000 GHz</td>
<td>13.7500000000 GHz</td>
</tr>
</tbody>
</table>

**Source**

Click a button to launch the External Devices dialog where you can select an internal or external source to be used for the VNA LO source or VNA RF source.

- **Cancel** Closes dialog box without saving changes.

- **OK** Saves the configuration and the **VNA is Preset** before making the appropriate settings.

- **About MM...** Displays information about the current hardware configuration.

**Mixer Mode**

Mixer measurements can be made at mmWave frequencies using **SMC**. (VMC measurements are NOT supported.)

Beginning with A.09.40, mixer measurements can be made with a 2-port test set connected to a 4-port PNA-X. This configuration yields a 2-port mmWave system. [Learn about 2-port system connections and limitations.](#)

Before A.09.40, The Mixer Mode checkbox could be enabled ONLY when the number of VNA test ports matched the number of ports on the mmWave test set. This means that an N5261A (2 port test set) could ONLY be connected to a 2-port VNA and an N5262A (4-port test set) could ONLY be connected to a 4-port VNA.

**Procedure**
1. Connect your DUT to the mmWave system as described below.

2. Configure this dialog (Millimeter Module Configuration). Check **Mixer Mode**, then press **OK**. This presets the VNA.

3. **Create an SMC measurement.**

4. **Make mixer settings.** As with standard SMC measurements, only two DUT ports can be swept in frequency. The remaining DUT port must be a fixed frequency. **See configuration used for harmonic mixers.**

5. **Increase power** for mmWave modules that are connected directly to a VNA port or external source.

6. Calibrate using the **SMC Calibration Wizard with mmWave Power Control.**

**Hardware Connections for Mixer mode**

The following image shows the standard connections from a N5261A or N5262A test set port to a mmWave module.

mmWave mixers usually require that two of the three mixer ports operate at mmWave frequencies. When **Mixer Mode** is checked on this dialog (Millimeter Module Configuration), the following restrictions apply:

- **On a 2 port mmWave system**, only **port 1** of the test set can be used as a mmWave frequency port. Port 2 can **NOT** be used.

- **On a 4 port mmWave system**, only **ports 1 and 3** of the test set can be used as mmWave frequency ports. Ports 2 and 4 can **NOT** be used.

- **The SMC parameter** being measured must be within the frequency range of the VNA or within the frequency range...
range of the banded mmWave module. Frequencies in between these ranges are allowed by the SMC mixer setup dialog, but the measurement results on the screen are NOT accurate.

Connections with a 4-port mmWave system

**Upconverters**

- DUT Input - Connect to VNA port 2 or port 4.
- DUT LO - Connect mmWave module to test set Port 3.
- DUT Output - Connect mmWave module to test set Port 1.

**Downconverters**

- DUT Input - Connect mmWave module to test set Port 1.
- DUT LO - Connect mmWave module to test set Port 3.
- DUT Output - Connect to VNA port 2 or port 4.

Connections with a 2-port mmWave system

Although supported, testing mmWave mixers with a 2-port system can be challenging for the following reasons:

- Testing mmWave mixers requires that two of the three DUT ports be at mmWave frequencies.
- Only test set port 1 is capable of adequately driving a mmWave module when used as a receiver.
- Therefore, the second DUT port that requires mmWave frequencies must have the mmWave module connected directly to an external source or a VNA second source.
- When using the mmWave module as a source, only the DC Bias and RF cable is necessary. The LO cable to the mmWave module is NOT used. This is because the RF input frequencies are multiplied in the mmWave module to provide the source frequencies. So a mmWave module used as a source can use the RF cable to connect directly to the VNA second source or an external source. About +5 dBm of RF power is required to adequately drive the mmWave module.

**Downconverters** - requires two mmWave modules as sources

- DUT Input - Connect the mmWave module to the test set port 1.
- DUT LO - Connect the RF cable of the mmWave module to an external source or the VNA (SRC2) second source.
- DUT Output - Connect to VNA port 2.

**Upconverters** - requires a mmWave module as a **source** at the DUT LO and a mmWave module as a **receiver** at the DUT Output:

- DUT Input - Connect to VNA port 2.
- DUT LO - Connect the RF cable of the mmWave module to an external source or the VNA (SRC2) second source.
- DUT Output - Connect the mmWave module to the test set port 1.

**Measuring Harmonic Mixers**

Harmonic mixers have a multiplier circuit in the LO port of the DUT. Enter the multiplier value in the numerator of the X LO port in the **SMC mixer setup dialog**. This will provide the correct LO frequencies out of the appropriate source.

**Spectrum Analyzer mmWave Measurements**

Beginning with A.10.45.xx, spectrum analyzer measurements can be made at mmWave frequencies using the Option S93090xA **Spectrum Analyzer** application plus Option S93093A/B or Option S93094A/B. Broadband and banded mmWave measurements are supported. The test set configuration is required for both.

Options S93093A/B and S93094A/B are mmWave measurement options specific to the Spectrum Analyzer application. Broadband measurements require Option S93093A/B and measure from 10 MHz to = 110 GHz. Banded measurements require Option S93094A/B and measure frequencies > 110 GHz.

**Note:** The **IF Response Adjustment** must be performed each time a new configuration is set up or if cables are changed.

The following procedure outlines the steps required to set up a spectrum analyzer mmWave measurement.

1. Configure the mmWave measurement using the **Millimeter Module Configuration** dialog.
2. On the VNA front panel, press **Meas > S-Param > Meas Class...**
3. Select **Spectrum Analysis**, then either:
   - **OK** delete the existing measurement, or
• New Channel to create the measurement in a new channel.

4. A Spectrum Analysis measurement is displayed. Learn about setting up a Spectrum Analyzer measurement.

5. Select other mmWave supported measurement classes as needed.

**mmWave Module Power Level Control**

Beginning with A.09.40, the following TWO features are integrated into Guided Cal:

- For S-parameter Cal - Use Multiple Sensors
- For SMC Cal - Power Table

The following table shows features that can be used to provide leveled power to the input of your DUT for S-parameter and SMC measurements.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>Use when...</th>
<th>Use for...</th>
<th>Access the feature...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Receiver leveling</td>
<td>Provides a sweep-to-sweep leveled power.</td>
<td>Works anytime.</td>
<td>S-params and SMC</td>
<td>Before or after Cal</td>
</tr>
<tr>
<td>Use Multiple Sensors</td>
<td>Allows several power sensors to be used to calibrate source power.</td>
<td>You require more than one power sensor to complete the source power calibration of the measurement frequency range.</td>
<td>S-params and SA</td>
<td>During Guided Power Cal</td>
</tr>
<tr>
<td>Power Table</td>
<td>Build or use a file that contains data of mmWave module output power vs frequency.</td>
<td>A power sensor is NOT available for calibration of the mmWave modules being used.</td>
<td>S-params</td>
<td>During Std Source Power Cal</td>
</tr>
<tr>
<td>Calibrate the source at multiple power levels</td>
<td>Source power is measured using the specified power meter/sensor or VNA receiver to construct a</td>
<td>A component is used in the source path which does not have NOT linear gain or loss over frequency.</td>
<td>S-params</td>
<td>During Std Source Power Cal</td>
</tr>
</tbody>
</table>

6801
If you have one or more power sensors that spans the frequency range of your measurement, then use the following process.

Otherwise, perform a standard Source Power Cal. Learn how.

**Using one or more power sensors**

Check ALC Enabled (if available) on the Millimeter Module Configuration dialog.

1. With an S-parameter measurement active, press Cal > Smart Cal....

2. On the following Select Ports dialog, check Calibrate source and receiver power, then click Next.

3. **Important:** In the following dialog, check Use Multiple Sensors, even if using only one sensor.

4. Complete the Guided Cal process.

**Note:** During the 'Connect a power sensor to port n'...step, the following error message may be displayed:

The default power level of 11 dBm is unachievable after calibration. Lower the power before starting calibration.
This means that a high amount of loss was measured in the path, and 11 dBm at the test ports will not be possible.

**Cancel** the calibration and lower the source power level using the **Power and Attenuators dialog**.

**Perform a standard Source Power Cal - S-parameter measurements**

When one or more power sensors that span the frequency range of your S-parameter measurement are NOT available, then use the following process.

**Note:** Perform an S-parameter calibration AFTER performing the following Source Power Cal.

1. Check **ALC Enabled** (if available) on the **Millimeter Module Configuration** dialog.

2. Press **Cal > Main > Other Cals > Source Power Cal...** then **Options...** to launch the following dialog:

   ![Source Power Calibration Options](image)

   **See the help topic for this dialog**

3. If one does not already exist, create a power table to be used to calibrate the VNA receiver. [Learn how](#).

4. Check **Use a power table and the analyzer reference receiver**.

5. Click **Power Table**, then navigate to the *.prn file.

6. Click **OK**.

7. Check **Calibrate the source at multiple power levels**.

8. Click **Power Levels...**, then enter the Max power, Min power, and Step Size at which source power should be
corrected. Be sure that the source power for your measurement is within these power levels. Otherwise, source power will NOT be accurate. Learn more about this feature.

9. Check Calibrate the analyzer reference receiver, then click OK.

10. On the Source Power Cal dialog, click Take a sweep. The output of the test set is set to Max power and a sweep is performed to calibrate the reference receiver.

11. Power is dropped for several subsequent sweeps. The calibrated reference receiver is used to fully characterize the source power.

12. The entire correction table can be saved along with the instrument state in a *.csa file. Learn how.

13. Power out of the input module should be flat and accurate.

SMC Cal

Use the following calibration process to achieve accurate, leveled power at the mmWave test ports.

1. With a configured SMC measurement active, Cal > Main > Smart Cal....

2. At the SMC Calibration Setup dialog, when a Thru standard is NOT available, check Independent power cals for input and output ports (no thru).

3. On the Select Ports dialog, check Calibrate source and receiver power, then click Next.

4. At the following Power Cal settings dialog:

   ![Power Cal Settings dialog](image)

   Learn about this dialog

   a. When you have ONE power sensor that spans the frequency range of your SMC measurement, then click Power Meter Settings to configure the power sensor. There are currently NO provisions for using multiple power sensors with SMC Calibration.

   b. Otherwise, use the following Power Table process.

      i. If one does not already exist, create a power table to be used to calibrate the VNA receiver.
Learn how.

ii. Check **Use Power Table**.

iii. Click **Power Table**, then navigate to the *.prn file. The selected *.prn file is annotated to the dialog.

iv. Click **OK**.

5. If you checked **Independent power cals for input and output ports (no thru)**, you will ALSO be prompted to select a power table for Port 2.

6. Complete the **Guided SMC Cal** process.

---

**Power Table**

**Note:** This is NOT the same table that is used for the **Calibrate the source at multiple power levels** feature.

A power table is a text file with data that describes the output power of the module as a function of frequency. This is valid when the mmWave module is driven at high levels (+11 dBm). This file may have been created for you by a third party or shipped with your mmWave Module. If not, you can create this *.prn file from the manufacturer's specification for the mmWave module.

This file can be created manually, using a text file program such as Notepad. Copy the header information, and create the file with two columns, one for frequency and one for output power.

---

</table>
**Example .prn file**

*Note:* With Rev. 09.31, the first line of the *.prn file must have the Input power at which these measurements were made. Otherwise, an error message appears with the default value that will be assumed. See above image for format.

---

**Using Cal All Wizard for Supported mmWave Measurement Classes**

Beginning with A.10.45.xx, the Cal All Wizard can be used to calibrate broadband and banded configurations.

A power table can be used instead of multiple power sensors to cover a wide frequency range. In addition, a power table can be used when the measurement frequency exceeds the frequency range of the power sensor (typically > 110 GHz). Refer to Power Table for information on how to create a power table.

The power table file name must be **powertable1.prn**, where "1" corresponds to the port number. This file must be stored in the following directory on the VNA:

C:\ProgramData\Keysight\Network Analyzer\Configurations\<configuration name>\%

where **configuration name** is a directory name that is also the name of the currently selected configuration in the Millimeter Module Configuration dialog.

Once the power table has been created and saved to the directory shown above, it will be listed in the Sensor drop down menu in the Power Cal Settings dialog where it may be selected instead of a power sensor.

1. Check ALC Enabled (if available) on the Millimeter Module Configuration dialog.

2. Ensure that the measurement classes to calibrate are active.

3. Press **Cal > Main > Other Cals > Cal All...** to launch the following dialog showing the active measurement classes:
4. Select the ports, click **Next**, then confirm or change the calibration properties in the **Measurement Class Cal Properties** dialog.

5. Click **Next** to access the **Calibration Attenuator Settings** dialog.

6. In the **Calibration Attenuator Settings** dialog, perform the following:
   
   a. Set the attenuator settings. Learn more.
   
   b. Click on the **Noise Reduction** button to improve measurement accuracy. Learn more.
   
   c. Click on the **Mechanical Devices** button to view all switches and attenuators in the VNA. Learn more.

7. Click **Next**, then select the DUT connectors and calibration kits in the **Select DUT Connectors and Cal Kits** dialog.

8. Click **Next** to access the **Power Cal Settings** dialog.

9. In the **Power Cal Settings** dialog, perform the following:
   
   a. Check **Use Multiple Sensors** if more than one power sensor is needed to cover the frequency range then select a sensor from the **Sensor** drop down menu.
   
   b. Otherwise, check **Use Multiple Sensors** then select the power table from the **Sensor** drop down menu. Learn how to create a power table.
c. Learn more about **Accuracy Tolerance** and **Max Number of Readings**.

10. Click **Next** and follow the calibration process until completed.
mmWave Measurements without a Test Set

This topic describes the basic configuration needed to connect a waveguide transmission reflection frequency extender directly to a PNA-X (without a N526x test set). This configuration will allow you to create an integrated 2-port banded waveguide S-Parameter measurement solution. In particular, it will focus on the options and configurations of the PNA-X as well as the settings required to make a complete measurement.

- Requirements and Limitations
- Hardware Connections
- VNA Settings

See Also

mmWave Configuration with a N526x Test Set

Requirements

- 4-port PNA-X, or 2-port / 2-source PNA-X
- Option S93080A FOM. Learn more about FOM.
- Firmware A.09.00 or greater
- mmWave Modules
- DC Power Supply for mmWave Modules
- mmWave Cal Kit

- The frequency extenders being used should have the following basic architecture. This is an example of the OML modules, although other frequency extenders maybe used.
The key parameters to be aware of are:

- Ensure that the PNA-X being used has sufficient drive power for the RF and LO signals. Since most frequency extenders typically operate in a saturated mode the PNA-X has sufficient RF port power to drive the OML, VDI, and Farran frequency extenders.

- The IF output of the frequency extenders to the receiver input is less than the compression level of the PNA-X.

Limitations

- This configuration is limited to S-Parameters only.

- Log Sweep is not allowed.

Hardware Connections
The following list of components applies to the example shown above:

- Dual Source PNA-X N5242 with option 400 include option S93080A FOM
- Quantity 2 of 75-110 GHz Transmission Reflection Modules N5256A.
- DC Power Supply 12V at least 3 Amp to drive 2 Frequency Extenders E3632A.
- Special Module cables N5260AK48 quantity 2, these include all the RF, LO, IF and special DC cable for the OML module used.

Connect the frequency extenders to the VNA as shown below:

- This shows how one mmWave module is configured. When used with a 2-port PNA-X, the internal second source is used instead of port 3.
- This same principal is used to configure the second mmWave module using ports 2 and 4.
Remove the jumper cables, then connect to the Receiver IN connectors.

<table>

VNA Settings

**Note:** A macro is available that makes the following VNA settings automatically. [Learn more.]

1. In **Power and Attenuators** dialog:

   ![Power and Attenuators](image)

   a. Set the Port 3 and Port 4 power to ON. (This allows LO power to always be ON).
   
   b. Adjust the port power to adequately drive the mmWave module (12 dBm is this example).
   
   c. Clear the **Port Powers Coupled** checkbox if the LO and RF power requirements are different.

2. In **Path Configuration** dialog, Set Port 1 Ref Switch to **External**. This is NOT necessary for rear-panel connections and on a second mmWave module connected to ports 2 and 4.

   ![Path Configuration](image)

3. In **FOM** dialog:

   **Note:** The following procedure shows mmWave frequencies from 75 GHz to 110 GHz.
To make the following Multiplier, Divisor, and Frequency settings, click in the Settings field for the corresponding Source or Receiver, then click Edit.

b. Receivers: Set Offset to 100 MHz and Multiplier to 0.
c. Source 2 (LO): Set Offset to 12.5 MHz and Divisor to 8.
d. Set all modes to Coupled.
e. Check Frequency Offset: ON
f. Set Primary: Start 75 GHz - Stop 110 GHz
g. Set X-Axis Display Annotation to Primary.

4. In Calibration Preferences dialog: To calibrate at the mmWave frequencies check the Use FOM Primary Frequency.

Using the Macro

Using the macro will eliminate all of the steps involved in setting up the power and the attenuators as well as the Frequency settings. Download the macro from the following URL http://na.support.keysight.com/pna/apps/mmwave_setup.msi.

Load the macro and enter the values for setting up the measurement.
The N5264B is a PNA-X with no Source Ports or Tunable receivers. This makes the N5264B a very fast and very sensitive IF receiver that has been designed specifically for antenna and radar cross-section (RCS) measurements. When used with external sources, the N5264B can make frequency-scan measurements of antennas, or make RCS measurements in time domain.

- **N5264B Options and Limitations**

- **Configuring the N5264B**
  - IF Receivers
    - Internal LO Source (Opt 108)
  - External Sources
  - How to Create Measurements
  - Calibrating the N5264B

- **See Also**
  - FIFO and other Antenna Features
  - Antenna Selection Guide
  - 85309 Manual updated for VNA -P/N 85310-90002
  - Antenna and RCS Measurement Configurations
  - N5264B Specs
N5264B Options and Limitations

The N5264B has the following options:

- **IF Receiver** (base model) - The A, B, C, D, and R receivers are always set at the specified IF frequency.

- **IF Receiver + LO source** (Opt 108) - In addition to the receiver-only option, this option adds a 10 MHz to 26.5 GHz LO source.

- **Fast-Sweep / FIFO Mode** (Opt S93118A/B) - These features together allow you to make very fast measurements and save the data to a remote computer. Learn more.

Limitations

The following VNA features are NOT available on the N5264B

- No Source ports

- No S-Parameters - Arbitrary ratioed parameters ARE allowed.

- No Application support

- Limited Calibrations
Configuring the N5264B

IF Receivers

- The five IF receiver inputs are on the N5264B rear panel.
- All five IF receivers are measured at the same time. However, only those measurements that are displayed are updated.
- External mixers are always required to down-convert signals to the IF frequency.
- The default IF frequency for the N5264B is 7.605634 MHz.
- Change the IF frequency to any value between +14.9999 MHz and -14.9999 MHz using SENS:IF:FREQ (SCPI) or IFFrequency (COM) commands.

Internal LO Source (Option 108) - 10 MHz to 26.5 GHz

The LO source output connector is on the N5264B rear panel.

The power level of the internal LO source is typically about +10 dBm and can NOT be changed.

To change the frequency of the LO Source:

1. Change the IF frequency of the measurement if necessary.
2. On the FOM dialog, change Receivers frequencies to the RF frequency range to be measured.
3. The LO Source frequency range is set automatically. This frequency value can not be viewed.

External Sources

Because the N5264B has no internal sources (except for the optional LO), newly created measurements are displayed with a source port = 0 (zero).

External sources can be configured so that they are controlled by the N5264B. Learn how to configure an external source.

Once configured, all existing and new measurements are changed to use the external source as the source port. When two or more sources are configured, the first configured source is displayed by default.

The external source settings can be changed from the following dialogs:

- Power and Attenuators dialog - Controls the ON | OFF state (set to Auto by default) and Power level of the external source.
• **FOM dialog** - Controls the frequency range. External sources are listed by name and uncoupled by default.

**How to Create Measurements**

Create ratioed and unratioed measurements using the standard **Receivers tab**.

S-parameters are not available.

**Calibration**

The only calibrations available are Response, Source Power and Receiver calibrations.

These are performed from the **Unguided Cal Wizard**.
Configure an External Device

Once configured (as shown in this topic), an external device will appear in, and be controlled from, relevant VNA dialogs as though it were internal to the VNA.

- **External Device** Configuration dialog

The following (separate) topics discuss how to set properties for these types of devices:

- External Source Properties
- Power Meter As Receiver (PMAR) Properties
- External Pulse Generator Properties
- Configure an SMU (Source/Measure Unit)
- Configure a DC Source/Meter
- Drivers for External Compound Sources

---

**How to access the External Device Configuration dialog**

VNA Applications have additional methods of launching this dialog.

See Remotely Specifying a Source Port

---

**External Device Configuration** dialog box help
Important Notes

- This dialog is used to configure the following types of external devices:
  - External Source Properties requires FOM S9x080A, S9x082A or Option 009
  - Power Meter As Receiver (PMAR) Properties
  - External Pulse Generator Properties
  - DC Power Analyzer
  - SMU (Source/Measure Unit)

- To configure an external source using this dialog, your VNA must have FOM Option. Without this option, you must control an external source manually. See Synchronize an External Source for help with manual source control.

- By default, an external device is **de-activated** when the VNA is Preset or when a Instrument State is recalled. This behavior can be changed with a Preference setting so that it remains active through a Preset or Instrument State recall.

- External Device properties are NOT saved in an Instrument State file. However, the reference to the External Device from relevant VNA dialogs IS saved. Therefore, recalling a state file that refers to a device that is NOT present will result in a “Device configuration not found” error.

- Multiple configurations for the same physical device can be Active. However, only one configuration for the same external source can have the I/O Enabled.

- The driver for the P9336A USB I/Q Arbitrary Waveform Generator must be installed in the PNA. The driver can be downloaded from the Keysight website.

- The B2902A or N6705C driver names cannot be the same as the device name because the driver
names are reserved. For example, a device name of "B2902SMU" when using the B2902A driver is acceptable.

**External Devices**

The devices that are currently configured appear in this list. The number of devices that can be configured is limited by the specified Interface.

**New** Click to create a new device configuration. The default name is Device\(<n>\), where \(<n>\) is the next number for 'Device'.

**Remove** Click to remove the selected device from the list.

**Properties**

**Name** Enter a device name as it will appear when referring to this device in VNA dialog boxes. Edit the name at any time. Duplicate names are not allowed.

- Because External Devices can be used with FOM ranges, do NOT name an external device any of the following FOM range names: "primary", "receivers", or "source", "source1", "source2", "source3" and so forth. Learn more about FOM ranges.
- Do NOT use a parameter name such as "S11" or "R1".
- **DC Analyzer devices MUST use at least three characters in the name.**

**Device Type** Select one of the following:

(Quotes are used when specifying in a remote program.)

- "DC Meter" - Learn more
- "DC Source" - Learn more
- "Power Meter" (PMAR) - Learn more
- "Pulse Generator" - Only the Keysight 81110A Pulse Generator is supported. Learn more
- "SMU" - Learn more
- "Source" (RF) - Learn more
- "None" - returned remotely before setting Device Type.

**Driver** Select the appropriate model to be configured.
(Quotes are used when specifying in a remote program.)

For **Source** Device Type choose from:

("AG" is short for Agilent.-

- "AG81150_1" (Legacy driver with no modulation capabilities)
- "AG81150_2" (Legacy driver with no modulation capabilities)
- "AG81150_2S" (Legacy driver with no modulation capabilities)
- "AG836XX" (8360 and 8340)
- "AGESG" (ESG)
- "AGEXG" (EXG) See configuration note
- "AGGeneric" For sources that are NOT listed but can be controlled using SCPI. Click Device Properties, then Edit Commands to send commands to these sources. Learn how.
- "Agile Vector Adapter" (Driver for N5192 and N5194 Agile Vector Adapters with modulation capabilities. These sources need to be inserted in a back loop of the PNA. The PNA provides the LO.)
- "AGMXG" (MXG) The MXG must have at least firmware A.01.44 for FOM power sweep to work correctly.
- "AGPSG" (PSG)
- "HP834XX" (Driver for HP 834XX)
- "KtUXG" (Legacy driver for N5193)
- "M8190" (M8190A Arbitrary Waveform Generator with E8267D PSG Vector Signal Generator) Learn more .
- "M8190 + IQ mixer" (M8190A Arbitrary Waveform Generator with I/Q Mixer) Learn more .
- "M9336" (M9336A PXIe I/Q Arbitrary waveform Generator)
- "MXG_Vector" MXG driver that supports modulation for vector MXGs.
- "PSG_Vector" (PSG driver that allows modulation)
- "VXG" (M9383B/84B VXG Microwave Signal Generator)
- "VXT_Vector" (VXT driver with modulation capabilities)
- "M9383A" (PXIe Microwave Signal Generator)
- "P9336a + PSG " (P9336A USB I/Q Arbitrary Waveform Generator with E8267D PSG Vector Signal Generator)

For **SMU** Device Type, choose from:

- "B29xx" - B2900 Series
"N67xx" - N6700 Series

All other device types have only one driver.

Active - Show in UI  Check to make the device available for use in the relevant dialogs. An instrument state that is saved with an Active device (checked) will include the device in the state file. Otherwise, if the Active box is cleared, the device will NOT appear in the state file. Learn more about Instrument State files.

Note: The preset makes this disable. Check this again if necessary after preset.

Enable I/O  Clear this box to disable communication with the selected device. Do this to configure a device that is not yet connected to the VNA.

- Communication with devices is attempted when Enable I/O is checked, Active is checked, and OK is pressed.
- When communication is attempted, devices with Enable I/O checked are queried for selected limits, such as frequency, power, and number of points. If there are limit problems, the VNA sends an error and the affected channels are put into Hold. These limits are enforced by the dialog box in which they are set. Resolve the reported limit problem and then restore the triggering.
- If communication with a device is lost the affected channels are put into Hold.

Device Properties  Click to launch the Properties dialog for relevant Device type:

- Configure External Sources
- Configure a Power Meter As Receiver
- Configure an External Pulse Generator
- Configure a DC Meter / Source
- Configure a SMU

IO Configuration

Type VISA address that is used to connect the device to the VNA.

The "..." button opens the Select VISA Resource dialog box.
**Interactive I/O.** Open the interactive I/O of Connection Expert.

Select in Resource Finder from the following selections, then click **Find**.

- **GPIB** - Devices connected to the System Controller GPIB port.
- **USB** - Devices connected to the VNA USB ports. See Important First-time USB connection note.
- **Aliases** - Devices that are connected to ANY interface for which you created an alias. See Configure Alias and LAN devices.
- **LAN** - Devices connected to a network using a LAN connection. The VNA must also be connected to the network.

**Note:** Devices connected to LAN must first be configured in Keysight IO libraries before they will appear on the Available list. See Configure Alias and LAN devices.

**Configure Alias and LAN Devices**

Use this procedure to configure a device using a LAN interface. Also use for ANY device for which you want to set an alias (easily-recognized) name. The alias name appears in the Available field when Aliases is selected as the Interface.

1. On the VNA, minimize the VNA application (**System > Main > Minimize Application**).
2. In the system tray (lower-right corner) right-click the IO icon, then click **Keysight Connection Expert**.

To Add a LAN Device:
1. In Keysight Connection Expert, click Manual Configuration tab.

2. Select LAN Instrument.

3. Click, then enter the IP address of the external source.

4. Click Test This VISA Address to verify communication.

5. Click Accept.

To create an Alias for a connected device:

1. In the list of connected instruments, click the instrument, then click Add or Change Aliases.

2. Enter the Alias Name to be used in the External Device Configuration dialog.

Drivers for External Compound Sources

Drivers have been created to facilitate the configuration of external source devices commonly used for specific types of measurements such as Spectrum Analyzer (SA) or Modulation Distortion (MOD or MODX). The following is a list of the current drivers for these sources:

- **M8190** (M8190A Arbitrary Waveform Generator with E8267D PSG Vector Signal Generator)
- **M8190 + IQ mixer** (M8190A Arbitrary Waveform Generator with I/Q Mixer)

**M8190A Arbitrary Waveform Generator**

The M8190A configuration can be with or without an embedded CPU. However, the preferred M8190A is the configuration without an embedded CPU using a PCIe cable connection to the PNA. A special cable is required: PCIe 4-lane to PCIe 8-lane. In this configuration, the driver must be installed in the PNA for the driver to be seen by the CPU in the PNA. This makes the cable connection to the M8190A an extension of the memory domain of the PNA CPU. This configuration is several times faster than using the USB interface.

The M8190A must have at least one of the following options:

- **M8190A-14B** - 8 GSa/s with 14 bit resolution
- **M8190A-12G** - 12 GSa/s with 12 bit resolution

**Note:** Power up the M8190A first and wait until the LED on the front-panel is lit (green) before powering up the PNA.
M8190A Preferred Model (without CPU)

M8190A Outputs

The Direct Out outputs are used by the M8190 driver and the Amp Out outputs are used by the M8190 + IQ mixer driver.

M8190 Compound Source Driver
The **Driver** name is **M8190**.

**M8190 Device Properties**

In the dialog above, **M8190PSG** is the name assigned to the **M8190** driver. With **M8190PSG** highlighted in the **External Devices** window, de-select the **Active - Show in UI** check box, then click on the **Device Properties...** button to access the following dialog:

**Note:** Before changing the configuration of this driver, the **Active - Show in UI** must be de-selected. After changes are made and this dialog is closed, check the **Active - Show in UI** check box when ready to activate the driver. Otherwise, the setting changes will not be applied.
**Timeout (sec)** Sets the VISA timeout and will stop processing additional SCPI commands on the first error and will put the measurement into hold.

**Dwell per point (ms)** Applies a dwell in Hardware List triggering ONLY. Set the time (in milliseconds) the external source will wait before data acquisition.

**PSG I/O Configuration** - Sets the VISA address of the PSG.

**Amplitude I/Q** - Sets the amplitude of the I and Q differential outputs from the M8190A. Calibration affects these settings. The M8190A **Direct Out** outputs are connected to the PSG using four cables of the same length.

**DC Offset I/Q** - Sets the offset to remove any LO feedthru.

**8 GSa/s 14bits (14B option)** - Selects the Option M8190A-14B.

**12 GSa/s 12bits (12G option)** - Selects the Option M8190A-12G.

**Digital Upconverter (DUC)** - Selects the Option M8190A-DUC.

**M8190 + IQ Mixer Compound Source Driver**
The **Driver** name is **M8190 + IQ mixer**.

**M8190 + IQ mixer Device Properties**

In the dialog above, **M81_IQ** is the name assigned to the **M8190 + IQ mixer** driver. With **M81_IQ** highlighted in the **External Devices** window, de-select the **Active - Show in UI** check box, then click on the **Device Properties...** button to access the following dialog:

**Note:** Before changing the configuration of this driver, the **Active - Show in UI** must be de-selected. After changes are made and this dialog is closed, check the **Active - Show in UI** check box when ready to activate the driver. Otherwise, the setting changes will not be applied.
**Time out (sec)** Sets the VISA timeout and will stop processing additional SCPI commands on the first error and will put the measurement into hold.

**Dwell per point (ms)** Applies a dwell in Hardware List triggering ONLY. Set the time (in milliseconds) the external source will wait before data acquisition.

**RF output** - Selects the IQ mixer output. Select *Straight Out, no PNA port* to go out of the IQ mixer and not controlled by the PNA, or select one of the PNA ports. The PNA port selections will set the proper path and step attenuation in the PNA automatically. If *Straight Out, no PNA port* is selected, the IQ mixer output can still be connected to the PNA, but path and step attenuation must be set manually.

The following shows a configuration example where Port 1 (J11) is the source of the LO drive signal and the RF Output of the IQ mixer is re-injected into PNA Port 1 (J10) on the rear panel:
Source power offset - Sets the power offset applied at the source driver level. If a decent value of the RF path budget between the modulated source and the DUT port is set (negative value means attenuation, positive value means amplification: there is power booster added in the path), then (even without modulation power level calibration) the source requested power and the source obtained power at the DUT plane will be aligned.

IQ Mixer LO drive - Selects the LO signal source for the IQ mixer from any PNA port, an external source, or baseband (no LO drive signal). One of four possible M8190A baseband outputs (output of DAC) can be selected: DC or AC output of Channel 1, or DC or AC output of Channel 2.

Power - Sets the power of the LO signal.

Source I/O Configuration for external source LO drive - Sets the address of an external source when used as the LO signal source.

Amplitude I/Q - Sets the amplitude of the I and Q differential outputs from the M8190A. Calibration affects these settings. The M8190A Amp Out outputs are connected to the PSG using four cables of the same length.

DC Offset I/Q - Sets the offset to remove any LO feedthru.

8 GSa/s 14bits (14B option) - Selects the Option M8190A-14B.

12 GSa/s 12bits (12G option) - Selects the Option M8190A-12G.

Digital Upconverter (DUC) - Selects the Option M8190A-DUC.
External Source Configuration

Once configured, an external source appears in VNA dialogs as though it were an internal source. This capability requires FOM Option S93080A.

In this topic:

- How to Configure an External Source
- Important Notes
- Trigger Settings and Physical Connection diagrams
- Generic Source Commands dialog

### How to Configure an External Source

1. **Important:** Create an External Source device by name (one-time). [Learn how](Separate topic).
2. Then click **Device Properties** to **Configure the External Source**. (This topic)

VNA Applications have additional methods of launching this dialog.

#### Using Hardkey/SoftTab/Softkey

<table>
<thead>
<tr>
<th>Using Hardkey/SoftTab/Softkey</th>
<th>Using a mouse</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Press <strong>Setup</strong> &gt; <strong>External Hardware</strong> &gt; <strong>External Device...</strong></td>
<td>1. Click <strong>Instrument</strong></td>
</tr>
<tr>
<td>2. Click <strong>Device Properties</strong> to <strong>Configure the External Source.</strong></td>
<td>2. Select <strong>Setup</strong></td>
</tr>
<tr>
<td>3. Select <strong>External Hardware</strong></td>
<td>3. Select <strong>External Hardware</strong></td>
</tr>
<tr>
<td>4. Select <strong>External Device...</strong></td>
<td>4. Select <strong>External Device...</strong></td>
</tr>
</tbody>
</table>

See [Remotely Specifying a Source Port](#)

**External Source Configuration** dialog box help
This dialog box is used to make external source settings.

**Important Notes about External Sources**

- First create an External Source (device) by name (one-time). [Learn how](#). (Separate topic)

- Once you create and activate an external source from the Configure an External Device dialog, it becomes available from the following VNA dialog boxes as well as the softkeys and entry toolbar, as if it were an internal VNA source. **Use the following dialogs to set the state, frequency, and power level of the external RF source:**
  - Power and Attenuators dialog
  - FOM dialog
  - New Trace / Receivers tab dialog

- By default, an external source is **de-activated** when the VNA is Preset or when a Instrument State is recalled. This behavior can be changed with a Preference setting.

- External Keysight sources are usually limited to 1601 points with List-sweep mode. To 'work around' this limitation, divide the measurement among multiple channels. For example, to attain a sweep of 3200 points, create two channels of 1600 points. You can also use manual source control which
supports Step-sweep mode. In this mode an external source can have up to 65,535 points. See Synchronize an External Source for help with manual source control.

- External sources should always share the same 10 MHz Reference signal as the VNA. Connect a BNC cable from the VNA 10 MHz Ref Output to the External Source Input.

- All newly-activated sources are preset, with source power OFF. Source power must be turned ON in the Power dialog. Frequency Offset must be enabled in the FOM dialog.

- The same source can NOT be used more than once in the same channel.

- The VNA automatically controls all trigger settings for the external source.

- See EXG Sources configuration note.

### Source Settings

**Timeout (sec)** Sets the VISA timeout and will stop processing additional SCPI commands on the first error and will put the measurement into hold.

**Dwell per point (ms)** Applies a dwell in Hardware List triggering ONLY. Set the time (in milliseconds) the external source will wait before data acquisition.

**Enable Modulation Control** - Enables modulation of an external modulation source to be controlled from a source dialog.

**Check Lock of Reference Clock IN** - (SA and Modulation Distortion source drivers) Checks for the VNA's reference clock at the external source. The reference clock is checked at external source driver startup. If the clock is not available, an error message is displayed. If a dual hardware source is used (for example, M8190+PSG), the reference clock inputs of both sources are tested. In the case of the USB chassis (P9336A), the reference clock is tested at the rear 10 MHz chassis input if the P9336A 10 MHz chassis reference is selected.

**Edit Commands** Provides a method to send SCPI commands to AGGeneric (not listed) sources.

### Trigger Settings and Physical Connection diagrams

**Note:** The VNA controls ALL external source trigger settings automatically (except for those on this dialog). All settings in the External Trigger dialog are ignored.

**Trigger Mode**

**Software CW (GPIB)** Slowest method.

- The external source receives each CW frequency from the VNA over GPIB, USB, or LAN. No other trigger cables are required. Although a Trigger Port selection may be available, it is
NOT used.

**Hardware List (BNC)** Fastest method.

- NOT available for AGGeneric (not listed) sources.
- The external source receives a list of CW frequencies from the VNA, then receives trigger signals though a rear-panel connector when appropriate from the VNA.
- If the number of data points used in the measurement exceeds the capability of the external source, the VNA automatically switches to Software CW (GPIB) trigger mode. This will slow the measurement significantly.

**Trigger Port** Used ONLY for Hardware List Trigger Mode. Select the VNA rear panel connector to be used for triggering. The sources must be connected as follows:

- For ONE or TWO external sources, connect each source to an AUX trigger pair. See rear panel Aux connectors.
  - Source Trig Out connects to VNA Aux Trig In
  - Source Trig In connects to VNA Aux Trig Out

The following diagram shows the connections between the PNA (AUX TRIG 1 or 2 can be used) and N519xA UXG signal generator.

- For more than TWO sources, some will need to be connected using the following daisy chain image. For example, with three external sources, two could be daisy-chained to Aux 1 while the third is connected by itself to Aux 2.
Notes

- Source 1, which receives the trigger out of the VNA, must be the first source listed on the External Devices Configuration dialog box. Devices are listed in the order in which they are created. You may have to delete, then re-create a source to move it down on the list.

- Connect **EXG sources** as follows:
  
  - EXG rear-panel label TRIG 1 connects to VNA AUX TRIG 1 OUT
  - EXG rear-panel label TRIG 2 connects to VNA AUX TRIG 1 IN

**Note:** The VNA AUX TRIG 2 can be used instead of VNA AUX TRIG 1.
Enter the SCPI commands that control the following functions on your AGGeneric (not listed) source. A field without a SCPI command entered will be ignored and that function will not be set.

To launch this dialog, click **Edit Commands** on the **External Source Properties** dialog.

**Operation Complete (**OPC)**.

**Preset**  Presets the source

**Set CW Frequency**  Sets CW Frequency

**Set CW Sweep Mode**  Sets source sweep mode

**Set Power**  Sets source power

**Set Power State**  Turns power ON or OFF
Configure DC Sources and DC Meters

Once configured, one or more DC Sources and DC Meters can be controlled by the VNA. DC Power Analyzers are also supported, but they must be configured as a separate Source and Meter.

The Keysight N6700 series and B2900 series DC Analyzers are supported with configuration files that can be loaded on the DC Meter and DC Source property page. Once loaded, the SCPI commands that control the DC device can be modified and saved. Learn how.

See Also

External DC Meter Data Conversion

How to Configure a DC Meter or DC Source

1. **Important**: Create a DC Source / Meter device by name (one-time). Learn how (separate topic).

2. On the Configure an External Device dialog, click **Device Properties**. (This topic).

<table>
<thead>
<tr>
<th>Using Hardkey/SoftTab/Softkey</th>
<th>Using a mouse</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Press <strong>Setup &gt; External Hardware &gt; External Device...</strong></td>
<td>1. Click <strong>Instrument</strong></td>
</tr>
<tr>
<td>2. Click <strong>Device Properties</strong> to Configure the External Source.</td>
<td>2. Select <strong>Setup</strong></td>
</tr>
<tr>
<td></td>
<td>3. Select <strong>External Hardware</strong></td>
</tr>
<tr>
<td></td>
<td>4. Select <strong>External Device...</strong></td>
</tr>
</tbody>
</table>

Once configured, set the DC source voltage and display DC meter measurements:

- **DC Sources**: DC Source control is available in Standard, Gain Compression/GCX, and FCA channels.
  
  - Set the Start and Stop voltage on the **DC Control dialog**. To access this dialog: Press **Sweep > Source Control > DC Source**.

- **DC Meters**: DC meter measurements are available in Standard, Gain Compression /GCX, Swept IMD / IMDX, and FCA channels.
  
  - In **Gain Compression /GCX, Swept IMD / IMDX, and FCA channels**, display DC parameters as you would an RF parameter, by clicking **Trace > New Trace**.
In a Standard channel, configure an unratioed measurement. See AUX tab.

**DC Source / Meter Configuration** dialog box help

The DC Source and DC Meter properties are almost identical in how they operate. Both are documented here.

### Device Settings

**Timeout** - Sets a time limit for the DC source or meter to make contact with the VNA. If this time limit is exceeded, the VNA stops the measurement and displays the following error message.

**EXECUTION ERROR; OPC QUERY TIMEOUT ERROR**

If this occurs, check the connections between your VNA and external device.

**Dwell Before Sweep**  
Wait time before making a sweep.

**Dwell After Point**

- **DC source**  
  Wait time after setting the voltage/current at each data point.

- **DC meter**  
  Wait time before measuring voltage/current at each data point.

**Type:** This setting changes the units that are displayed in the DC Source dialog, the X-axis display annotation, and the underlying data format. Use these settings with Receiver or Source Correction (Scaling and Offset) to display and scale measurements with these units. Choose from:
V (volts - default)        dBm
A (amperes)               W (watts)
F (degrees)               C (degrees)
K (kelvin)

**Note:** To change the X-axis to display the DC Meter units, click **Response**, then **Display**, then **Labels**, then **Select X-Axis**, then select the DC Meter.

**Receiver / Source Correction**

- For a **DC source**, use the correction settings to scale and offset the output voltage.
- For a **DC Meter** (receiver), use the correction settings, along with Type, to display and scale measurements with appropriate units. For example:

  Measure the voltage across a 5 ohm resistor, then display the results in A(mperes).

  Using ohms law,  \( I = \frac{V}{5 \text{ ohms}} \) or \( I = V * 0.2 \)

  For receiver correction, enter **Scaling** = 0.2; **Offset** = 0.

**ON** Check to apply the following correction factors to each measurement.

**Offset**: Enter the value to offset the DC Meter reading or set the DC Source voltage.

**Scaling**: Enter the value to scale the DC Meter reading or set the DC Source voltage.

\[
\text{Displayed Output} = \left( \frac{\text{Measured}}{\text{Set value}} - \text{Offset} \right) \times \text{Scaling value}.
\]

**Edit Commands** - Click to start the Edit Commands dialog.

**Important Note:**

The Edit Commands dialogs (see below) MUST be completed. They are used to set the SCPI commands with which the VNA communicates with the DC device.

These commands are saved, along with other configuration settings, to configuration (*.xml) files. These files can then be loaded later when communicating with the same DC Device.

Configuration files for the Keysight N67xx and B29xx Power Analyzers and the other devices are pre-loaded on the VNA. Click **Load**, then navigate to: `c:\users\public\network analyzer\documents\drivers`. 
Save - Press to save the current DC Source or DC Meter configuration to an *.xml file. The list of files is NOT filtered by "DCMeter" or "DCSource", so use a descriptive filename.

Load - Press to load an existing configuration.

**DC Meter Edit Commands dialog box help**

**Global Tab**

The Global tab includes the system settings for the DC Meter.

**ID Query** - Enter the SCPI command to return the ID string of the DC Meter. Typically *IDN?

**Error Query** - Enter the SCPI command that is used to return DC Meter errors. Typically SYST:ERR?

**Enable I/O** - Enter the SCPI commands that is used to enable the DC Meter to read voltages.

**Disable I/O** - Enter the SCPI commands that is used to disable the DC Meter from reading voltages.
Test Connection

Click to start the Test Connection dialog. You must first have entered the I/O Configuration settings and select Enable IO on the External Device dialog.

Enter a SCPI command, then click **Send** or **Send&Read** when a return value is expected.

Sweep Tab

Use the Sweep Tab to send SCPI commands to the DC Meter at the beginning or end of each sweep.

**Abort Sweep** - Enter the SCPI command that is used to Abort or reset the DC Meter. This would be necessary when the VNA sweep is aborted or terminated. The VNA will then send the command to the DC Meter.

Point Tab
**Read (commands)** - Enter the SCPI command that is used to make a DC measurement at each data point.

**Set (commands)** - Use `<%variable>` to make a DC Meter setting.

### DC Source Edit Commands dialog box help

**Global Tab**

The Global tab includes the system settings for the DC Source.

**ID Query** - Enter the SCPI command to return the ID string of the DC Source. Typically `*IDN`? This entry can be left blank.

**Error Query** - Enter the SCPI command that is used to return DC Source errors. Typically `SYST:ERR`?

**Enable I/O** - Enter the SCPI commands that is used to enable the DC Source to output voltages.

**Disable I/O** - Enter the SCPI commands that is used to disable the DC Source from outputting voltages.

### Maximum / Minimum DC Output

**Read Max / Min Using** - Select, then enter the commands used to return the output limits of the DC source.

**Define Max / Min As** - If the DC Source has no commands to return these values, or you would
rather define the limit for your DC Source, select then enter the Max and Min voltage limits.

### Test Connection

Click to start the Test Connection dialog. You must first have entered the I/O Configuration settings and select Enable IO on the External Device dialog.

![Test Connection dialog](image)

Enter a SCPI command, then click **Send** or **Send&Read** when a return value is expected.

### Sweep Tab

Use the Sweep Tab to send SCPI commands to the DC Source at the beginning or end of each sweep.

Typically, you might send the output ON at the beginning of each sweep, and output OFF at the end of each sweep as shown above.

**Abort Sweep** - Enter the SCPI command that is used to Abort or reset the DC Source. This would be necessary when the VNA sweep is aborted or terminated. The VNA will then send the command to the DC Source.

### Point Tab
Note: The DC Source output voltages are configured on the DC Source dialog.

This dialog is used to configure the commands that are used to communicate with the DC Source.

Set commands - Enter the SCPI command, enclosed in {curly brackets} to output (set) a voltage/current from the DC Source for each data point.

- {\%f} - The value is a double value. (Most common).
- {\%d} - The value is a integer. This would be used when the voltage controls a remote switch. For example, you can program the value to: "0,1,0,1,0,1,...". where "0" = OFF and "1" = ON.
Configure a Power Meter As Receiver (PMAR)

When a power meter is configured as a VNA receiver (in standard measurement channels ONLY), you can...

- Extend the number of measurement receivers.
- Use the power meter as a scalar detector.
- Monitor the power at any point in a measurement system.
- Use multiple power meters in a Guided Power Cal to cover a wide frequency range.

**Note:** Multiple configurations for the same physical device can be Active. However, only one configuration for the same external source can have the I/O Enabled

- Use the power meter to level the stimulus power at any point in a measurement system.
- Use the power sensor as a PMAR device to confirm the accuracy of a Source Power Cal. Learn how.

**Note:** PMAR is not compatible with Point Sweep mode.

Once configured, a power meter can be used like any other VNA receiver in the following dialogs:

- New Trace / Meas dialog - used in Ratioed and Unratioed measurements.
- Receiver Leveling
- Frequency Offset Mode - Extend frequencies beyond VNA

See Also

- Supported Power Meters
• Important first-time USB connection note.

How to Create and Configure a PMAR Device

1. Create a PMAR device by name (one-time).
2. Then click Device Properties to configure the Power Meter/Sensor.

VNA Applications have additional methods of launching this dialog.

<table>

External Device Configuration dialog box help

This dialog allows you to create and configure a power meter to be used as a receiver by the VNA. Once you create and configure a power meter from this dialog box, it becomes available from VNA dialog boxes as well as the softkeys and entry toolbar, as if it were an internal VNA receiver.

• This dialog is ALSO used to configure an External Source. Learn more.
To configure a single power meter for a Source Power Cal, use the **Power Meter Settings** dialog.

**Important Notes**

- By default, an external PMAR device is **de-activated** when the VNA is Preset or when an Instrument State is recalled. This behavior can be changed with a Preference setting so that it remains active through a Preset or Instrument State recall.

- PMAR configuration is NOT saved in an Instrument State file. Therefore, recalling a state file that refers to a device that has been removed, or recalling a state file on a different VNA will result in a “Device configuration not found” error.

**External Devices**

The devices that are currently configured appear in this list. The number of devices that can be configured is limited by the specified Interface.

**New** Click to create a new PMAR configuration. The default name is Device<n>, where <n> is the next number for 'Device'.

**Remove** Click to remove the selected device from the list.

**Properties**

**Name** Enter a device name as it will appear when referring to this device in all VNA dialog boxes. Edit the name at any time. Duplicate names are not allowed.

**Notes**

- Because External Devices can be used with FOM ranges, do NOT name an external device any of the following FOM range names: “primary”, “receivers”, or “source”, “source1”, source2”, "source3” and so forth. Learn more about FOM ranges.

- Do NOT use a parameter name, such as "S11, or "R1".

**Device Type** Select **Power Meter**.

**Driver** Use AGPM for all Keysight Power Meters. See Supported Power Meters

**Active** Check to make the device available for use in the FOM, New Trace, and Receiver Leveling dialogs. An instrument state that is saved with an Active device (checked) will include the device in the state file. Otherwise, if the Active box is cleared, the device will NOT appear in the state file.

**Note:** Multiple PMAR configurations for the same physical device can be Active and Enabled.
Device Properties  Click to launch the Configure Power Sensor dialog.

IO Configuration

Interface  Select the interface that is used to connect the device to the VNA. These devices will then appear in the 'Available' field. Choose from:

- **GPIB** - Devices connected to the System Controller GPIB port.
- **USB** - Devices connected to the VNA USB ports. See Important First-time USB connection note.
- **Aliases** - Devices that are connected to ANY interface for which you created an alias. See Configure Alias and LAN devices.
- **LAN** - Devices connected to a network using a LAN connection. The VNA must also be connected to the network. Note: Devices connected to LAN must first be configured in Keysight IO libraries before they will appear on the Available list. See Configure Alias and LAN devices.

Available  Shows a list of devices that are connected to the specified IO Interface.

Refresh  Click to rescan the specified interface for devices.

Selected  Enter the IO configuration or select from the available list of IO Interfaces found.

Enable I/O  Clear this box to disable communication with the selected device. You would do this to configure a device that is not yet connected to the VNA.

- Communication with devices is attempted when Enable I/O is checked, Active is checked, and OK is pressed.
- If communication with a device is lost, the affected channels are put into Hold.
- When communication is attempted, devices with Enable I/O checked are queried for limits for frequency, power, and number of points. If there are limit problems, the VNA sends an error and the affected channels are put into Hold. These limits are enforced by the dialog box in which they are set. Resolve the reported limit problem and then restore the triggering.
- Communication is also attempted when clicking the Settings button on the Configure Power Sensor dialog. You can not change any of the sensor settings unless Enable I/O and Active are checked and communication is possible with the sensor.

Configure Alias and LAN Devices

Use this procedure to configure a device using a LAN interface. Also use for ANY device for which you want to set an alias (easily-recognized) name. The alias name appears in the Available field.
when Aliases is selected as the Interface.

1. On the VNA, minimize the VNA application.

2. In the system tray (lower-right corner) right-click the IO icon, then click **Keysight Connection Expert**

To Add a LAN Device:

1. In **Keysight Connection Expert**, click **Manual Configuration** tab.

2. Select **LAN Instrument**

3. Click, then enter the IP address of the external source.

4. Click **Test This VISA Address** to verify communication.

5. Click **Accept**.

To create an Alias for a connected device:

1. In the list of connected instruments, click the instrument, then click **Add or Change Aliases**.

2. Enter the Alias Name to be used in the **External Device Configuration** dialog.

**Power Sensor Configuration** dialog box help

To launch this dialog, with the PMAR device selected in the **External Device Configuration** dialog, click **Device Properties**.
This dialog is used to configure a power meter / sensor for use as a receiver.

To configure a single power meter for a Source Power Cal, use the Power Meter Settings dialog.

**About Power Sensor Calibration**

PMAR traces are NOT calibrated using standard VNA calibrations, including response corrections.

PMAR traces are calibrated using methods that are appropriate for the selected sensor. Follow the proper guidelines for zeroing or calibrating the sensors that are in use. Check to ensure that the selected sensor is appropriate for the frequency range and the power level at which PMAR measurements occur.

The VNA does not automatically prompt you to perform a calibration.

To calibrate a power sensor, click **Settings** on this dialog box, then click **Zero/Calibrate Sensor**. Learn more.

**Note:** By default, a PMAR is de-activated when the VNA is Preset or when a Instrument State is recalled. This behavior can be changed with a Preference setting.

**Sensor**

For power sensors that are connected to a power meter, select a sensor to configure.

**Settings** Click to launch the Power Sensor Settings dialog.

When pressed, communication with the sensor is tested. Sensor settings can NOT occur unless **Enable I/O** is checked on the External Device Configuration dialog, and the sensor is properly connected and configured.

**Sensor Settling**

Each power meter reading is "settled" when either:

- two consecutive meter readings are within this Tolerance value or
- when the Max Number of Readings has been met.

The readings that were taken are averaged together to become the "settled" reading.

**Tolerance** When consecutive power meter readings are within this value of each other, then the
reading is considered settled.

**Max Number of Readings** Sets the maximum number of readings the power meter will take to achieve settling.

**Sensor Loss Compensation**

**Use Loss Table** Select this checkbox to apply loss data to Source Power calibration correction (such as for an adapter on the power sensor).

**Edit Table** Invokes the Power Loss Compensation dialog box.

**Power Meter Uncertainties**

**Uncertainty...** Select this button to set up power meter uncertainties for power uncertainty calibrations. Then, when the Use uncertainties option is selected during a guided calibration, uncertainty power values will include the uncertainty of the power meter.

Clicking on the Uncertainties... button opens a dialog to either select a specific power meter from a list or load a custom file of power meter uncertainties.

---

**Power Sensor Settings** dialog box help

This dialog appears when you click the Settings button on the Configure Power Sensor dialog.
**Note:** Be sure that the frequency range of your power sensor covers the frequency range of your measurement. This does NOT occur automatically.

**Sensor A (B)** Displays one of the following messages depending on type of sensor.

- **Not connected** The VNA is not detecting a power sensor.

- **Sensor Data** Allows the following entries for power sensor data:
  
  - **Reference Cal Factor** Specifies the Cal Factor for the 50 MHz reference signal.
  
  - **Cal Factor Table** Specifies the frequency and corresponding Cal Factor for the sensor.
  
  - **Delete Cal Factor** Deletes the indicated row in the table.
  
  - **Delete All** Deletes all data in the table.
  
  - **To Add a Row** to the table, click on a row in the table and press the down arrow on either the VNA front panel or keyboard. A row is added to the bottom of the table. The table is automatically sorted by frequency when OK is pressed.

- **Cal factors are contained within this sensor** Internal Reference Cal Factor and Cal Factor data are loaded automatically and the following dialog appears.

  ![Power Sensor Settings](image)

  - **Use Internal Cal Factors** This box only appears when internal cal factors have been detected for the sensor and by default will be checked. Clear this box to not use internal cal factors.

**Load Cal Factors** Click to load cal factors from a *.csv file that you create from the cal factors that appear on the sensor. The first line of the file MUST have the reference Cal Factor (typically...
100), followed by Freq / Cal Factor pairs as show in the following image:

**Save Cal Factors** Click to save the cal factor table to a *.csv* file.

**Limit Frequency Range**

- Check to limit the use of the power sensor to those within the Minimum and Maximum frequency values.

- Clear to use the power sensor for all measurements. If the measurement frequency is not within the Minimum and Maximum frequency values, the closest min or max correction data is used for the measurement.

**Minimum Frequency** Specifies the minimum frequency range for the sensor.

**Maximum Frequency** Specifies the maximum frequency range for the sensor.

**Zero and Calibrate the Power Sensor**

For highest accuracy, Zero AND Calibrate the power sensor before measuring data. Follow prompts that may appear.

**Zero** - If the following settings are 'greyed', Internal or External zeroing is selected automatically based on the power meter/sensor model. Otherwise, select the appropriate type of zeroing to perform, then press *Zero*.

- **Internal Zero** - A switch inside the power sensor removes the sensor from the incident power.

- **External Zero** - Requires that you physically remove the sensor from incident power.
Note for the U2000 Series USB power sensors

Calibration is NOT available. Select External Zero ONLY when the power to be measured is below the specified level. Otherwise, the U2000 series performs internal zeroing automatically when needed. See your power sensor documentation for more details.

- U200xA - below -30 dBm
- U200xH - below -20 dBm
- U200xB - below 0 dBm

If your U2000 power sensor 'hangs' when external zeroing, upgrade the power sensor firmware to Rev. A.01.02.00 or higher to fix this problem.

Calibrate - Available when the selected sensor has calibration capability. Calibration involves measuring an internal 1 mW source.

- Keysight P-Series sensors have an internal reference so you can calibrate them without connecting to the meter’s reference port.
- Keysight U2000 USB power sensors do not require calibrating.
- For other sensors, refer to the documentation to determine if it has calibration capability.

Press Calibrate, then follow the prompts.

Power Loss Compensation dialog box help

![Power Loss Compensation dialog box](image)
To Add a Row to the table, click on a row in the table and press the down arrow on either the VNA front panel or keyboard.

To Edit a value, double-click in the cell to be edited.

Compensates for losses that occur when using an adapter or coupler to connect the power sensor to the measurement port. These components will be removed when the calibration is complete. To account for components that will remain during the measurement, use the Power Offset setting.

The Frequency / Loss pairs define the amount of loss for the entire frequency range. For example, using the entries in the above dialog image:

- 0.5 dB is used to compensate power sensor measurements up to 1 GHz.
- Each data point between 1 GHz to 2 GHz is linearly interpolated between 0.5 dB and 1 dB.
- 1 dB is used above 2 GHz.
- A single frequency/loss segment is applied to the entire frequency range.

Beginning with A.09.80, enter up to 9999 segments to achieve greater accuracy. Previously the limit was 100.

Note: Large segment counts with one or more power sensors can result in long load and close times for the VNA Application.

**Frequency** Enter a frequency in Hz.

**Loss** Enter a loss as a POSITIVE value in dB. To compensate for gain, use NEGATIVE values.

**Delete Table Segment** Deletes row indicated in the field.

**Delete All** Deletes all data in the table.

The Power Loss Compensation table survives VNA Preset and Power OFF. To NOT use Loss compensation, clear the Use Loss table checkbox on the Configure Power Sensor dialog.

**Use a PMAR Device to confirm a Source Power Cal**

Learn how to create and configure PMAR device.

After a Source Power Cal has been performed, use the same sensor as a configured PMAR to analyze the accuracy of the Calibration.
1. Create a PMAR device with the power sensor that will be used for the Source Power Cal.

3. Create an unratioed measurement with the PMAR device. Learn how.

4. With the power sensor still connected to the test port, monitor the corrected source power using Min and Max markers or the Trace Statistics peak-to-peak feature.
Configure and Use External Pulse Generators

Once configured, one or more 81110A External Pulse Generators can be accessed from the VNA Integrated Pulse Application. The external pulse generators can be used without Opt. S93025A/B (internal pulse generators). However, the Integrated Pulse App is available ONLY with Opt. S9x025A/B.

Only the 81110A Keysight Pulse Generator is supported.

In this topic:

- How to Configure an External Pulse Generator
- Pulse Generator Configuration dialog box help
- Using External Pulse Generators with the Integrated Pulse App

See Also

Integrated Pulse Application

IF Path Configuration

81110A Quick Start Guide.

How to Configure an External Pulse Generator

1. **Important**: Create an External Pulse Generator device by name (one-time). Learn how (separate topic).

2. On the Configure an External Device dialog, click Device Properties (this topic).

Using **Hardkey/SoftTab/Softkey**

1. Press **Setup > External Hardware > External Device...**

Using a mouse

1. Click **Instrument**
2. Select **Setup**
3. Select **External Hardware**
4. Select **External Device...**

[Programming Commands]
Tip: In the External Device Configuration dialog, you can configure the same 81110A twice; once for each output module. For example:

- Name = "81110A-1" Output = Out1
- Name = "81110A-2" Output = Out2

Pulse Generator Configuration dialog box help

System Settings

**Time out** - Set the amount of time allowed to communicate with the external pulse generator. If communication has not been established before this amount of time has elapsed, a Timeout message will appear. Check connection settings on the External Device dialog.

**Primary Mode** - When checked, the 81110A trigger mode is set to Internal. This also causes the 81110A to appear as a selection on Integrated Pulse App, Pulse Trigger setting. When selected here and on that dialog, the timing of configured 'follower' pulse generators is controlled by the 81110A pulse generator. Although more than one configured pulse generator can have the Primary Mode setting checked, only one pulse generator can be connected to the rear-panel Pulse connections. Learn more about making physical connections.

When this setting is cleared, the 81110A trigger mode is set to External and can be configured as a 'follower' pulse generator to the VNA internal pulse generators or another external pulse generator.

Output Settings

The following are 8110A settings made by the VNA. Some settings may not be possible depending on the modules that are installed on the 81110A. Please refer to the 81110A Quick Start Guide for...
Using External Pulse Generators with the Integrated Pulse App

Once configured, an external pulse generator can be used with the Integrated Pulse App as though it were an internal pulse generator.

N1966A Pulse I/O Adapter. See an enlarged view of the IF Block diagram

An External Pulse Generators can be used for ONE OR MORE of the following pulsed functions within the Integrated Pulse Application.

- Modulate the sources
- Drive the IF (Receiver) Gates (Narrowband mode ONLY).
- Trigger the ADC to make receiver measurements (Wideband mode ONLY).

How to Modulate a Source with an External Pulse Generator

When using an external source modulator (Z5623AH81):
Connect: the 8110A to the Z5623AH81 as shown in the Narrowband Pulse topic.

Setting: On the Pulse Generator Setup dialog, disable (clear) the Internal Pulse Modulators.

When using internal source modulators, the external pulse generator can drive the internal modulators in two ways:

- 81110A directly to the internal pulse modulators.
  - Connect: 81110A to RF Pulse Mod In on the N1966A OR rear-panel Pulse I/O connector.
  - Setting: On the Pulse Generator Setup dialog, set Modulator Drive to "External".

- 81110A drives internal pulse generators, which drives the internal modulator.
  - Connect: 81110A to Pulse Sync IN, on the N1966A OR rear-panel Pulse I/O connector.
  - Settings:
    - On the Pulse Generator Configuration dialog (above) check Primary mode.
    - On the Pulse Setup dialog, set Pulse Trigger to <ext pulse gen name>.

How to Gate IF Receivers with an External Pulse Generator

(Used ONLY in Narrowband mode.)

When IF Gating is used, the external drive can be routed in two ways:

- 81110A drives gates directly at the rear-panel IF Gate inputs.
  - Connect: 81110A to the Pulse IN for one or more VNA receivers on the N1966A OR rear-panel Pulse I/O connector.
  - Setting: On the Pulse Setup dialog, under Measurement Timing, for the receivers to be gated, set Pulse Gen to <ext pulse gen name>.

- 81110A drives the internal generators, which drive the gates.
  - Connect: 81110A to Pulse Sync IN, on the N1966A OR rear-panel Pulse I/O connector.
  - Settings:
    - On the Pulse Generator Configuration dialog (above) check Primary mode.
    - On the Pulse Setup dialog, set Pulse Trigger to <ext pulse gen name>.
On the Pulse Setup dialog, under Measurement Timing, for the receivers to be gated, set Pulse Gen to the internal pulse generator (Pulse0 through Pulse4) to be used to pulse the Rcvr<n>. Set unique pulse Width and Delay for the Receiver.

**How to trigger the ADC with an External Pulse Generator**

(Used ONLY in Wideband mode).

Pulse0 may be used to trigger the ADC. The following shows how P0 may be driven by an external pulse generator.

- **Connect:** 81110A to Pulse Sync IN, on the N1966A OR rear-panel Pulse I/O connector.

- **Settings:**
  - On the Pulse Generator Configuration dialog (above) check Primary mode.
  - On the Pulse Setup dialog, set Pulse Trigger Source to <ext pulse gen name>.
  - On the Pulse Setup dialog, under Measurement Timing, for the receivers to be triggered, set Pulse Gen to Pulse Trigger. Set Delay for the Receivers.
Configure an External SMU

An external SMU Source Measure Unit is a combined DC Source and Meter. The VNA supports the Keysight B2900 series and N6700 series of SMUs. Only the B2900 series offers Hardware Triggering (learn more).

Learn more about the Keysight SMU offerings at: http://Keysight.com/find/smu

For all other External DC devices, select DC Source or Meter Device Type. Learn more about configuring those devices.

How to Configure a SMU

1. **Important:** Create an SMU by name (one-time). Learn how (separate topic).

2. On the Configure an External Device dialog, click **Device Properties.** (This topic).

### Using Hardkey/SoftTab/Softkey

<table>
<thead>
<tr>
<th>Using a mouse</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Click <strong>Instrument</strong></td>
</tr>
<tr>
<td>2. Select <strong>Setup</strong></td>
</tr>
<tr>
<td>3. Select <strong>External Hardware</strong></td>
</tr>
<tr>
<td>4. Select <strong>External Device...</strong></td>
</tr>
</tbody>
</table>

Once configured, set the SMU source voltage and display Voltage / Current Meter measurements:

- **SMU Sources:** DC Source control is available in Standard and Gain Compression/GCX channels. Set the Start and Stop voltage on the **DC Control dialog.** To access this dialog:
  
  - Press **Sweep > Source Control > DC Source...**

- **SMU Measure:** DC measurements are available in Standard and Gain Compression/GCX channels.
  
  - In Gain Compression/GCX channels, display DC parameters as you would an RF parameter, by pressing **Trace > Trace Setup > Measure...**

  - In a Standard channel, configure an unratioed measurement. Press **Trace > Trace Setup > Measure... > Receivers.** For Numerator, select the external (or internal) DC meter.

  - Change the X-axis to display the DC Meter parameters by pressing **Sweep > Main > X-axis Type,** then select the DC Meter.
To start this dialog, on the External Device Configuration dialog, select SMU as the Device Type. Then click Device Properties.

SMU Information

The DC device names for six DC devices are listed. The names are made from the root device name (given in the External Device Configuration dialog) plus a suffix.

In the above image (example):

- **Device0** is the root device name.
- **"_Src1"** means voltage source of channel 1.
- "\text{VM1}\" means voltage meter of channel 1.
- "\text{AM2}\" means current meter of channel 2.
- Check \text{Chan} \langle n \rangle to enable that channel in the SMU device.
- \textbf{Module Selection} selects the SMU module in the B1500A mainframe to use for the channel.

<table>

</table>

\textbf{Trigger Settings}

\textbf{Trigger Mode}: Choose from:

- \textbf{Software CW (GPIB)} Slowest method. The SMU receives each stimulus voltage from the VNA over GPIB, USB, or LAN. No other trigger cables are required.
- \textbf{Hardware List (BNC)} Available ONLY in B2900 series. Fastest method. The SMU receives a list of stimulus voltages from the VNA, then receives trigger signals though a rear-panel connector when appropriate from the VNA.
Note: The B2900 series can store no more than 2500 data measurements. Therefore, this mode is NOT allowed when the VNA data points exceed 2500 points.

Note: Hardware List trigger mode is NOT supported in GCA 2D sweeps.

- **SMU Trigger In / Out** - Available ONLY when the trigger mode is Hardware List. Select the trigger in and trigger out pins on the B2900 digital I/O connector. Connect these pins to the either pair of VNA AUX IO IN and OUT connectors. The VNA AUX trigger pair is automatically selected.

---

**External SMU - Source / Voltage / Current Meter** dialog box help

The descriptions for this dialog pertain to the Source, Voltage, and Current Meter tabs. Exceptions are highlighted.

**SMU Chan**  Select the SMU channel for which the settings on this page apply.

**Source type (Source ONLY)**  Select either a voltage source or current source.

**Device Settings**

**Timeout** - Sets a time limit for the DC source or meter to make contact with the VNA. If this time limit is exceeded, the VNA stops the measurement and displays the following error message.

**EXECUTION ERROR;OPC QUERY TIMEOUT ERROR**
If this occurs, check the connections between your VNA and external device.

**Dwell Before Sweep**  Wait time before making a sweep.

**Dwell After Point**

- **Source**  Wait time after setting the voltage/current at each data point.
- **Voltage / Current Meter**  Wait time before measuring voltage/current at each data point.

**Current / Voltage Limit** *(Source ONLY)*  Depends on the Source Type selection)  Sets the maximum current or voltage to be allowed from the source.

**Note:** To change the X-axis to display the Meter units, click **Response**, then **Display**, then **Labels**, then **Select X-Axis**, then select the SMU Meter.

**Receiver / Source Correction**

- For a **Source**, use the correction settings to scale and offset the output voltage or current.
- For a **Voltage or Current Meter** (receiver), use the correction settings to display and scale measurements.  For example:
  
  Measure the voltage across a 5 ohm resistor, then display the results in A(mperes).

  Using ohms law,  \( I = \frac{V}{5 \text{ ohms}} \) or \( I = V \times 0.2 \)

  For receiver correction, enter Scaling = 0.2; Offset = 0.

**ON**  Check to apply the following correction factors to each measurement.

**Offset:** Enter the value to offset the Meter reading or set the Source voltage.

**Scaling:** Enter the value to scale the Meter reading or set the Source voltage.

\[
\text{Displayed Output} = \left( \frac{\text{Measured}}{\text{Set value}} - \text{Offset} \right) \times \text{Scaling value.}
\]

**Edit Commands**  - Click to start the Edit Commands dialog. This feature is usually not necessary with an SMU external device.

**Save** - Press to save the edited SMU configuration to an *.xml file. The list of files is NOT filtered so use a descriptive filename.

**Load** - Press to load an existing configuration.
The SMU Source and Meter Edit commands are almost identical in how they operate. Both are documented here.

Global Tab

The Global tab includes the system settings for the SMU Source.

**ID Query** - Enter the SCPI command to return the ID string of the DC Source. Typically *IDN? This entry can be left blank.

**Error Query** - Enter the SCPI command that is used to return DC Source errors. Typically SYST:ERR?

**Enable I/O** - Enter the SCPI commands that is used to enable the DC Source to output voltages.

**Disable I/O** - Enter the SCPI commands that is used to disable the DC Source from outputting voltages.

**Maximum / Minimum DC Output (Source ONLY)**

**Read Max / Min Using** - Select, then enter the commands used to return the output limits of the SMU source.

**Define Max / Min As** - If the SMU has no commands to return these values, or you would rather define the limit for your SMu, then enter the Max and Min voltage limits.
Test Connection

Click to start the Test Connection dialog. You must first have entered the I/O Configuration settings and select Enable IO on the External Device dialog.

Enter a SCPI command, then click **Send** or **Send&Read** when a return value is expected.

Sweep Tab

Use the Sweep Tab to send SCPI commands to the SMU at the beginning or end of each sweep.

**Abort Sweep** - Enter the SCPI command that is used to Abort or reset the SMU. This would be necessary when the VNA sweep is aborted or terminated. The VNA will then send the command to the SMU.

Point Tab
| **Read (commands)** - Enter the SCPI command that is used to make a DC measurement at each data point. |
| **Set (commands)** - Use `<%variable>` to make a DC Meter setting. |
Synchronize VNA/PNA-X with an External Source(s)

The VNA External Source Control feature can be used to automatically control external sources. However, this feature requires certain VNA options. Learn more.

Many VNA measurements require the use of at least two sources. If your VNA has only one internal source, an external source is required. For example, when measuring the insertion loss of a mixer, the LO must be swept at the same time as the RF input. This requires the VNA and external source to be synchronized.

The following procedure shows how to automatically synchronize the VNA/PNA-X with an Keysight external sources.

**Hardware configuration**

- Connect the VNA and External Source(s) Time Base (VNA/PNA-X 10 MHz OUT to External Source 10 MHz IN)

Connect the AUX Trigger I/O connectors as follows (for two sources):

- VNA/PNA-X AUX Trig-1 IN to External Source-1 Trigger OUT
- VNA/PNA-X AUX Trig-1 OUT to External Source-1 Trigger IN
- VNA/PNA-X AUX Trig-2 IN to External Source-2 Trigger OUT
- VNA/PNA-X AUX Trig-2 OUT to External Source-2 Trigger IN

Learn more about the AUX Trigger capabilities.

**VNA/PNA-X Settings**

- Refer to External Source Configuration

**What is Happening?**

The following is a flow diagram showing the handshake / synchronization process between the VNA/PNA-X and an External Source.
1. VNA/PNA-X loads frequency points and source power information onto the external source(s).

2. A trigger signal from the source starts the first data point of the measurement.

3. VNA/PNA-X data acquisition (measurement) starts, and then stops AFTER the first data point acquisition.

4. The VNA/PNA-X sends a trigger signal out to the source telling it to move to the next frequency data point.

5. The external source and VNA/PNA-X move to the next data point. The source usually takes longer than the VNA.

6. The source sends the Ready for Trigger signal to the VNA/PNA-X for next data acquisition.

7. Back to step 4 until last data point.
E5092A Test Set Control

- Overview
- Connecting the E5092A
- How to make E5092A test set Control Settings
- Calibrating with the E5092A

Other System Configuration Topics

Overview

The E5092A multiport test set can be controlled with the firmware of the 4-port PNA Series, 4-port E5080, and M980xA PXI VNAs with more than 4 ports (assuming the port-1 to 4 are connected to the E5092A). The E5092A control functions of GUI settings or corresponding SCPI commands can switch the E5092A’s RF paths and the control line outputs at the beginning of each channel’s sweep. These E5092A control functions associated with the channel are available only in the standard class.

Notes:

- To control the E5092A with the M980xA firmware, the M980xA firmware must be A.15.xx.xx and above, and the S94702A AMX VNA Plugin license is required in the PXI controller.
- The E5092A can be controlled only with the single firmware instance.
- The switching of the test set paths and control line outputs occurs just before the channel is triggered. If the channel trigger state is Hold, the switching for that channel does not occur.
- In addition to the E5092A control functions associated with the channel, there are SCPI commands which switch the E5092A’s RF paths and control line outputs independently of the channel when the commands are executed (CONTrol:MULTplexer commands). These commands are effective in the measurement classes other than the standard class.

Connect and Configure the E5092A

The E5092A can be connected to any one of the VNA USB ports. When first installed, Windows will automatically launch the "Add New Hardware" wizard. Click Next to install the E5092A test set.
Note: See the power handling limitations of the VNA USB ports.

Connect the VNA test ports to the E5092A test ports. Match VNA test port 1 to E5092A test port 1, and so forth.

Selecting ID for E5092A

The VNA can control up to two E5092A test sets. Set the Instrument ID bit switch to 1 or 2. The test sets will then be identified automatically and referred to by the DIP switch setting on the E5092A rear-panel. Change the ID bit switch setting before connecting to the VNA USB.

Power ON

Immediately after power-on, all of the port connection indicator LEDs of the E5092A go ON. Then, after the VNA detects the E5092A, the four LEDs that indicate the connected test ports remain ON. If the VNA is not powered on or if the E5092A is not connected using a USB cable, all of the LEDs stay ON.

How to make E5092A test set Control Settings

Using Hardkey/SoftTab/Softkey

1. Press Setup > External Hardware > External Testset > E5092A...

Using a mouse

1. Click Instrument
2. Select Setup
3. Select External Hardware
4. Select External Testset
5. Select E5092A...
E5092A test set control dialog box help

The title of the dialog shows the test set model and ID number of the active test set.

Select ID  ID of the test set to be configured. Up to two E5092A test sets can be controlled. Click to change test set ID. Learn how to set the test set ID.

Enable Test Set Control  When cleared, port switching and control line settings are disabled. This selection affects all channels using the selected test set.

<table>
<thead>
<tr>
<th>Selection</th>
<th>Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>E5092_13</td>
<td>Select the 13-port configuration of the E5092A</td>
</tr>
<tr>
<td>E5092_16</td>
<td>Select the 16-port configuration of the E5092A</td>
</tr>
<tr>
<td>E5092_22</td>
<td>Select the 22-port configuration of the E5092A</td>
</tr>
<tr>
<td>E5092_28</td>
<td>Select the switching independently in the E5092A</td>
</tr>
<tr>
<td>E5092_X10</td>
<td>Select the 10-port full crossbar configuration of the E5092A</td>
</tr>
</tbody>
</table>

Show Test Set Property  When checked, a second row on the status bar appears which indicates the test set that is being controlled and the current port control selection. For example, the following image shows the status bar when controlling an E5092A test set.

A. Configured channel

B. Port Control settings for E5092A
C. Test set Label. E5092A control does not use this field. It is shared between Interface Control and External test set Control. The two labels are separated by /.

Control of the second status bar is completely separate from the first status bar, which is controlled from the View, Status Bar menu.

<table>
<thead>
<tr>
<th>Port Mapping Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Port Control and Control Line settings affect the channel of the active (selected) measurement. These settings will occur as the channel is being measured.</td>
</tr>
<tr>
<td>- Correction is NOT turned OFF when port mappings are changed. However, the calibration is NO LONGER VALID!</td>
</tr>
</tbody>
</table>

Control Lines  Specifies the values of individual control lines. These general purpose control lines on the test set front-panel can be used in your test setup. Each button toggles the control line HIGH and LOW. When first opened, the selections reflect the current control lines. See your test set documentation for more information about the control lines.

OK  When clicked, the changes to the dialog box are implemented and the port selections and control values are immediately sent to the specified test sets. The Port Control and Control line settings are stored with other channel data and used when those channels are swept.

Cancel  (or Escape) Changes to the dialog are not implemented and revert to the settings before the dialog box was opened.

Calibrating with the E5092A

The following are a few changes in the way you calibrate the VNA with the E5092A connected:

1. Create the measurements for the channel and configure the Port Control (switching) on the E5092A Test Set Control dialog box. Enable Show Test Set Property.

2. To calibrate, start the Calibration wizard and select a Calibration method (ECAL, SmartCal, Basic Cal).

3. Select the DUT connectors that are used at the E5092A measurement reference plane.

4. When prompted to connect a standard to a VNA port, instead connect the standard to the E5092A port as indicated on the test set status bar. For example, when the cal wizard prompts to connect the standard to port 1, if the status bar indicates A1 in the E5092_22 configuration, connect the standard to port A1 (5A) of the E5092A.
External Multiport Test Set Control

Test sets are designed to be controlled by the VNA. There is a switch matrix that is controlled over GPIB/LAN/USB interface. They are independent instruments and do not require the PNA/PNA-X.

The VNA with a test set controlled over the test set interface can run in either multiport VNA or standalone VNA mode.

You need to run in multiport VNA mode with option S93551A/B. You cannot use any application measurement class in this mode.

If you want to use an application measurement class with a test set attached to the PNA, you need to run in standalone mode. The VNA does not know the presence of the test set in this mode, and you can use any application measurement classes you wish, but keep in mind that losses through the test set may be significant. To ensure that the test set is routing signals to the PNA ports (and not the test set ports), create the VBS script shown below and run it on the analyzer.

```vbs
Set app = CreateObject("AgilentPNA835x.Application")
Set TS = app.GetExternalTestSetIO

TS.WriteData 0, 0
TS.WriteData 16, 0
TS.WriteData 32, 0
TS.WriteData 64, 0
```

- **Supported Test Sets**
  - Option S93551A/B
  - E5092A (separate topic)

- **Procedure**
  1. Connect Test Set
  2. Restart as Multiport
3. Optional External Test Set Control Settings

- External Test Set Control and other Functions

---

### Other System Configuration Topics

**Supported Test Sets**

The list of test sets that provide integrated solutions with the VNA is constantly growing. For a current list of supported multiport test sets, see [www.Keysight.com/find/multiport](http://www.Keysight.com/find/multiport)

**Option S93551A/B**

- **With** Option S93551A/B enabled on your VNA, **any supported multiport test set** (such as the U3042A E12) can be controlled directly from the VNA to make fully integrated measurements at ALL of the available test ports. To understand what test ports are available to source and receive, see the test set documentation.

- **Without** Option S93551A/B, basic operation depends on the number of VNA test ports.
  
  - For a 2-port VNA, configure two available test ports.
  
  - For a 4-port VNA, configure four available test ports.

Option 550 is no longer available.

**Note:** By default, the system logical test ports are mapped as follows:
- **Port 1** - VNA port 1
- **Port 2** - Test Set port 2
- **Port 3** - VNA port 2
- **Port 4** - Test Set port 4

The ports can be **remapped** using the Port Control Setting.

**Block Diagram of a 2-port VNA and N44xx Test Set**

Click one of the S-parameters to see switch and path changes. Because the test set does NOT contain receivers, **measurement speed** and **calibration** can be affected.
Procedure - How to enable full Multiport Capability

1. Enable Option S93551A/B.

2. Connect the test set to the VNA using the documentation that was shipped with the test set.

3. Restart as Multiport VNA

4. Make optional External Test Set Control Settings

Connect and Configure the Test Set

Connect the test set to the VNA using the test set documentation. Most test set documentation can
Test Set I/O-controlled test sets

Test sets that are controlled using the Test Set I/O connector have NO return communication capability. The VNA sends commands out the rear panel connector. It is assumed that the test set is responding appropriately. The "Active" LED, located on the test set front panel, should light when the test set is addressed in Multiport Mode or manual operation. When the test set is not in use, the Active LED will be OFF.

GPIB-controlled test sets

Connect the test set to the GPIB using one of the following methods:

- If the VNA will NOT be controlled by a remote computer using GPIB, then the test set can be connected directly to the VNA GPIB port. The VNA is automatically switched to System Controller mode.

- If the VNA WILL be controlled by a remote computer using GPIB, then learn how to connect the test set

Restart as Multiport VNA

How to Enable Multiport capability

**Note:** If Option S93551A/B has not been enabled, the following Multiport Capability menu selection will NOT be available.

Using Hardkey/SoftTab/Softkey

1. Press **Setup > External Hardware > Multiport > Multiport Configuration...**

Using a mouse

1. Click **Instrument**
2. Select **Setup**
3. Select **External Hardware**
4. Select **Multiport**
5. Select **Multiport Configuration...**

Multiport Restart dialog box help
See Also External Test Set Control and other VNA Functions

After the test set is connected and **VNA Option S93551A/B is enabled**, the following settings are used to enable Multiport operation.

**Test Set** Select the test set file to load. Only the files that are appropriate for use on that VNA model are displayed.

**To Add a new Test Set file:**

1. On the VNA, click **File**, then **Exit** to quit the VNA application.
2. Download the Test Set file from: http://na.support.keysight.com/multiport/testsetsupport.html/
3. Save it to the VNA c:\users\public\network analyzer\testsets
4. Start the VNA application.
5. Click **Instrument**, then **Setup**, then **External Hardware**, then **Multiport Config**.
6. In the Multiport Restart dialog, click **Restart as multiport VNA with this testset**.
7. The new test set should now be visible from the **Testset**: menu.

**Address** Enter the test set address if the test set is connected to GPIB. Connections over the Test Set I/O connector are determined by their sequence.

- **Restart as a standalone VNA**. The VNA shuts down and restarts as a standard VNA. If the test set is left connected to the VNA, switch the test set OFF, then back ON to ensure that the test set routes signals to ports 1 and 2 of the VNA. In this condition, there is more loss in the test paths than without a test set connected. If the power switch is OFF, there is SIGNIFICANTLY more loss in the test paths.

- **Restart as a multiport VNA with this testset**. The VNA shuts down and restarts as a multiport VNA with
the selected test set.

Click **OK** The VNA shuts down and restarts in the selected configuration.

To learn how to change port mapping, see Port Control.

**Problems**

If the VNA cannot find the test set, the following error is displayed on the VNA:

**GPIB ERROR Address xx cannot open VISA session.**

To correct the problem, verify the following:

- The test set is connected to the VNA using one of the methods described above.
- The correct test set address is set.
- The test set is turned ON.

**Important: After the problem has been fixed:**

1. On the External Test Set Control dialog, click Enable Test Set Control.
2. Restart Triggering - press **Trigger > Main > Continuous**.
3. The VNA again tries to find the test set.

**External Test Set Control Settings**

The following External Test Set Control Settings are used to configure Multiport test sets. For the N44xx test sets, the only setting that is necessary is port control.
How to access the External Test Set Control Settings

Using **Hardkey/SoftTab/Softkey**

1. Press **Setup > External Hardware > Multiport > Other Testset Setup...**

Using a mouse

1. Click **Instrument**
2. Select **Setup**
3. Select **External Hardware**
4. Select **Multiport**
5. Select **Other Testset Setup...**

---

**External Test Set Control** dialog box help

![External Test Set Control dialog box](image)

**Important Notes:**

- With Option S93551A/B, **first** use the **Multiport Restart** dialog to **Restart as Multiport VNA with this test set.** The test set file is loaded and the test set is enabled automatically.

- When using GPIB to control an external test set, the VNA is automatically put in **System Controller mode.**

- See also **External Test Set Control and other VNA Functions**
Select ID

- For N44xx test sets: the GPIB address
- For other Multiport test sets: either GPIB address or 0 for Test Set I/O controlled test sets.

Enable Test Set Control When cleared, port switching and control line settings are disabled. This selection affects all channels using the selected test set. When checked, the 'Show Test Set Properties' checkbox is also checked automatically.

Load Test Set File For operating without Option S93551A/B.

If your Test Set is not visible, see Add a new Test Set.

The selected test set file is loaded.

1. Navigate to the folder: C:\Program Files(x86)\Keysight\Network Analyzer\testsets\  
2. Select a test set control file.

The title of the dialog shows the model of the test set file that is currently loaded.
See a list of supported test sets.

Show Test Set Properties This box becomes checked by default when the Enable Test Set Control is checked. When checked, a second row on the status bar appears which indicates the test set that is being controlled and the current port control selection. For example, the following image shows the status bar when controlling an E5091A test set and a Z5623A K64 test set:

A. Configured channel
B. Port Control settings for E5091A
C. Port Control settings for Z5623A K64
D. Test Set Label. This field is shared between Interface Control and External Test Set Control. The two labels are separated by /.

Control of the second status bar is completely separate from the first status bar, which is controlled from the View, Status Bar menu.

Test Set Label NOT available with option S93551A/B. Add text to appear on the second status bar
when **Show Test Set Properties** is checked. See image above.

**Port Control** Controls **mapping** of Physical ports to Logical ports. *(Refer to image of dialog box above.)*

- Physical ports are the port numbers that are labeled on the test set front panel.
- Logical ports are the port numbers that are referred to by most of the VNA application prompts and dialog boxes.

**Port Mapping Notes**

- Port Control and Control Line settings effect the channel of the active (selected) measurement. These settings occur as the channel is being measured.
- Correction is turned OFF when port mappings are changed.
- After the physical ports are mapped to logical ports, all VNA references to port numbers refer to LOGICAL port numbers. The only exception to this is during calibrations.

**Control Lines** For use with the U30xxA test sets. Specifies the values of individual control lines. These general purpose control lines on the test set front-panel can be used in your test setup. Each button toggles the control line HIGH and LOW. When first opened, the selections reflect the current control lines. See your test set documentation for more information about the control lines.

**OK** When clicked, the changes to the dialog box are implemented and the port selections and control values are immediately sent to the specified test set. The Port Control and Control line settings are stored with other channel data and used when those channels are swept.

**Cancel** (or Escape) Changes to the dialog are not implemented and revert to the settings before the dialog box was opened.

---

**External Test Sets and other VNA Functions**

The following features may work differently with a test set connected to the VNA.

**Remote Commands**

- See **SCPI** and **COM** commands for controlling an External Test Set.
- Use `*OPT?` (SCPI) or `NumberOfPorts` (COM) to query the number of ports for a VNA/External Test set.
- Use **logical receiver notation** to refer to double-digit ports.

### Sweep Settings

To compensate for additional cable lengths:

- Set to Stepped sweep
- Set **Dwell time** to at least 5 microseconds.

### Interface Control

When both **Interface Control** and External Test Set Control are configured, the commands on the Interface Control **Before Sweep Start** tab are sent out before any External Test Set Control commands are executed on that channel. Similarly, commands on the **After Sweep End** tab are sent after Test Set Control commands.

### Calibration

With an External Test Set connected, calibration is performed exactly like a VNA with the following exceptions:

- Correction is turned OFF when port mappings are modified. This also applies to Source Power Cal.
- Beginning with VNA Rev. A.07.50, for **TRL Cal**, **QSOLT**, or **Unknown Thru** cals with external test sets:
  - Use of a **Delta Match Calibration** from a User Cal Set is NOT required. However, for PNA-L models that require Delta match, a **Global Delta Match Cal** must be present. The Global Delta Match Cal can only be performed in stand-alone mode.
  - You can **NOT** perform any of those 3 cal types on **JUST** a pair of ports that share a test port receiver, such as Port 1 and Port 2 of a 4-port system. You would need to include an additional port in the calibration.
- With an External Test Set connected, you may be required to perform more than **3 THRU connections**.
- A test set such as the Z5623A K44 which is used with 4-port VNA models, does not terminate ports that are not currently in the source path. Because a ports load match on this system is not constant for all possible ports it can be paired with, when calibrating more than two total ports it may be necessary to make Thru measurements on more than the usual minimum number of Thru paths for a VNA calibration. The VNA will ensure that multiport calibrations use a sufficient set of Thru paths so that the calibration can correct for those variations in load match on this type of multiport system.
- As with ALL VNA calibrations, when error correction is **ON**, both forward and reverse sweeps are required for **EACH** port pair that is corrected, even if only one reflection measurement is displayed. For example, any displayed measurement with full 4-port calibration **ON** will require 12 measurement sweeps. **Learn more.**
**Source Power Cal**

*Source power calibration* involves adjusting the source so that the power at an output port is flat across a frequency range. Because of additional loss through some of the test set paths, it may NOT be possible to obtain corrected output power because of limitations on the source signal.

During a Source Power Cal, you are prompted when and where to connect the power sensor. When one of the supported test sets are connected, the prompt refers to the PHYSICAL port number, NOT the LOGICAL port number. To help with translating physical to logical port mappings, enable *Show Test Set Properties*.

**Measurements with Shared Receivers**

External test sets do not contain receivers. The VNA receivers are always used to measure signals at the external test set ports. Therefore, when a channel contains two measurements that share a VNA test port receiver, additional sweeps are necessary.

For example, to make S34 and S44 measurements in the same channel with correction OFF:

- On a 4-port VNA, only ONE sweep is required using the C (port 3), D (port 4), and R (reference for All receivers).
- On a N44xx system, TWO sweeps are required since both measurements use the B and R2 receivers. See interactive block diagram above.

**Create Ratioed and Unratioed Measurements**

When using an external test set, it IS possible to create a Ratioed measurement using two logical receivers that share the same physical VNA receiver. However, this measurement data is NOT valid. Invalid measurement traces show all data at -200 dB (in Log mag format). Learn about Logical Receiver Notation

**Logical Port References**

When an external test set is enabled, all references to VNA port numbers and test set port numbers (except during calibrations) refer to LOGICAL port numbers. Logical ports can be remapped using the *Port Control settings*. During a calibration, you are prompted to connect standards to physical port numbers.

**Balanced Port Mapping**

"Logical Ports" is a term that is used with both External Test Sets and balanced measurements. While the concept is the same, they refer to different scenarios. The two can be easily confused when making Balanced measurements with an External Test Set connected. The important principle to remember is the order in which the logical ports for each are mapped:
1. In the **External Test Set - Port Control settings dialog**, the physical VNA ports and test set ports are mapped to logical ports as noted above.

2. In the **Balanced Topology Dialog**, the new (step 1) logical ports are mapped again to become Balanced logical ports.

**Preset**

**Instrument Preset** will reset **Port Control** settings to defaults and remove the **test set label**. All other settings remain. To maintain port control settings and the test set label, create a **User Preset**.

**Instrument State Save and Recall**

**Instrument State files** include Test Set model, Enable and Status bar settings, and Port mappings and DUT control values for each channel.

If an Instrument State recall requires that a test set configuration file be loaded, recall time may be significant. For example, this would occur if a 2-port VNA with attached test set is configured as a 2-port VNA and then recalls a state file which requires 4-port operation.

**Recall Cal Sets**

If a Cal Set is saved while an external test set is enabled, when the Cal Set is recalled, then the external test set must be enabled or an error message is displayed.

**Copy Channel**

**Copy Channel** copies all relevant test set data from the source channel to the target channel.

**Applications**

No VNA applications are supported with External Test Set Control. These include FCA (opt S93083A/B), SMC (opt S93082A/B), GCA (opt S93086A/B), NFA (opt S93029A/B), Pulsed (opt H08).
Print

Port mapping information appears on the Channel Settings Table when printing.

Save sNP Files

To save sNP data with an external test set enabled, click File, Save As, then select Snp File(*.s*p), then complete the Choose ports dialog.
Display Colors

You can modify the colors that are used to draw various elements on the VNA screen and on a hardcopy print of the display.

See Also

Print Preview

How to modify DISPLAY Colors

These settings can also be accessed from the Preferences dialog box.

Using Hardkey/SoftTab/Softkey

1. Press System > System Setup > Preferences... > Colors....
2. Click Display Colors... in the Customize Display dialog box.

How to modify PRINT Colors

1. Press System > System Setup > Preferences... > Colors....
2. Click Print Colors... in the Customize Display dialog box.

Display and Print Colors dialog box help

The Display Colors and Print Colors dialog boxes function in exactly the same manner. See Print Preview procedure below.
"Pen" is a term used to describe the various elements. Each pen can have a unique color.

You can change the color of the following pens:

- **Background** - The background color of the inactive windows.
- **New Active Background** - The background color of the active window.
- **Grid** - The inner lines of all grids in all windows, and the grid frame in inactive windows.
- **Active Labels, Grid Frame** - The labels and grid frame colors in the active window. **Note**: when this pen is selected, the current window becomes inactive. Therefore, changes for this pen color will not be visible until **OK** is pressed.
- **Inactive Window Labels**
- **Failed Trace** - **Limit Line** failed traces or failure indicators (dots) and the word Fail.
- The following pens for up to 8 Traces:
  - **Data and Limits**
  - **Memory trace**
  - **Markers**
  - **Memory markers**

**About Trace Pens**

'1st Trace' is NOT always Trace1 (Tr1). For example, the first trace in a window might be Tr2 which is drawn with the "1st Trace" pen.

The first 8 traces are drawn with the defined pen colors. The next eight traces reuse the same colors, and so forth. For example, if all traces are numbered sequentially, the 9th and 17th traces are drawn using the same color as the 1st trace.

**Change Color**  Click the button or the color swatch to launch the **Change Color** dialog.

**Reset Color**  Restores the default color for the selected pen.

**Color Themes**

A theme is a complete set of pens and their colors. The current theme persists until you change it. Themes can also be saved to a file and then later recalled.
- **Save Theme**  Click to save the current set of pens to a file.
- **Recall Theme**  Click to recall and use a saved theme.
- **Reset Theme**  Click to recall the default VNA color theme.

The colors for the following Display elements can NOT be changed: toolbars, softkeys, menus, dialogs and popup messages.

---

**Change Color** dialog box help

To use a basic color, click the color from the 'Basic colors' palette, then click **OK**.

To define and use a custom color:

1. Click **Define Custom Colors>>** to open the right side of the dialog.
2. Optionally, pick a Custom color slot to replace. Otherwise, the replacement will occur at the first slot location and continue with subsequent custom color definitions.
3. Click the color pane, or drag the crosshairs, to the location of the custom color.
4. Drag the arrow to the desired saturation level of the custom color.
5. Click **Add to Custom Colors**
6. Continue to define more colors, or click **OK** to close the Color dialog.
After a custom color has been assigned to a VNA pen, the custom color can be changed. The VNA pen color remains unchanged.

**Print Preview Procedure**

Use the following procedure to preview your Print Colors on the VNA screen:

1. From the Print Colors dialog, select **Reset Theme** then **Save Theme**. Name the new theme “MyPrintTheme.colors”. This will give you a starting point equal to the default print colors.

2. Launch the Display Colors dialog, select **Recall Theme**, then select “MyPrintTheme.colors”. The display will now show the default print theme.

3. Customize the display colors. You will be previewing how the hardcopy will appear when printed.

4. Save the customized display colors to “MyPrintTheme.colors”.

5. Go to the Print Colors dialog and Recall “MyPrintTheme.colors.”
## Display Update

### How to set Display Update

**Using Hardkey/SoftTab/Softkey**

1. Press **Display > Display Settings > Display Update** (Turns ON display update).

2. Press **Display > Display Settings > click left side small button of Display Update** (Turns OFF display update).

### Notes:

1. Turn ON/OFF the Display update will result on the **Status Bar**.

2. Update State ON/OFF is part of the save/recall state.

3. Softkey(s) exist for update state ON/OFF and immediate update.

4. Disabling the display update will yield the most significant performance improvements. The performance improvement (due to disabling updates) for a single channel and window state seems negligible. However, with a large number of channels, windows and traces, it should make more of a difference (but disabling the display update will provide more performance improvement). For example, Performance Oddities, the following is looking at the INDEX line (Handler I/O) for a 1.0 GHz to 1.2 GHz with 201 point sweep (otherwise Preset condition apply). When high, the analyzer is sweeping. There is 20 ms of dead time between many of sweeps.
Mechanical Devices

- Overview
- How to access Mechanical Devices settings
- Mechanical Devices dialog

Other System Configuration Topics

Overview

**Note:** To prevent premature wear, the VNA does not allow attenuators or other mechanical switches to switch continuously.

These mechanical devices are set for the entire channel. When more than one channel is used, and a mechanical device setting is NOT the same for all channels, only the ACTIVE channel is allowed to sweep. All other channels are **Blocked** - NOT allowed to sweep. Blocked channels will resume sweeping when they are made ACTIVE, or when the conflict is resolved.

Press **Trigger > Main > Restart** to cause ALL channels to sweep once. Then the active channel will resume sweeping continuously.

The Mechanical Devices dialog shows the settings of all of the switches and attenuators in the VNA. The settings for all active channels are shown side-by-side for easy comparison. This dialog allows you to determine the settings which would cause mechanical devices to switch between states on consecutive sweeps, potentially leading to device wear-out. It also allows you to determine if the conflict can be resolved to enable continuous sweeps on all channels.

The following are the mechanical devices that are potentially shown in the dialog. These components may not appear in your VNA model:

- Port 1 through Port 4 Bypass Switches
- Port 1 through Port 4 Source Attenuator settings
- Receiver A through Receiver R Attenuator settings
- Port 1 Noise Tuner Switch and Port 2 Noise Receiver Switch
How to access Mechanical Devices settings

Using **Hardkey/SoftTab/Softkey**

1. Press **Setup > Internal Hardware > Mechanical Devices...**

Using **a mouse**

1. Click **Instrument**
2. Select **Setup**
3. Select **Internal Hardware**
4. Select **Mechanical Devices...**

Remote commands

SCPI:  `SENSe<cnm>:SWEep:BLOCked?`

COM: `IsBlocked Property`

---

**Mechanical Devices** dialog box help

See Mechanical Devices Overview (scroll up)

The devices that appear in the table depend on the VNA model and options.

> **Yellow** highlighted cell indicates the Active channel.

**Blue** highlighted cells indicate the following:

- The channel is NOT able to sweep. **Blocked** is shown in the top row.
The highlighted device settings differ from that of the sweeping channels.

To modify entries in the table, click a cell.

When a selection is changed, the new setting is applied immediately.

If Port Power is coupled, a dialog prompts if coupling should be turned OFF.

**Limitations**

- **Measurement Class** can NOT be changed from this dialog.
- The dialog does NOT report device settings for multiport test sets.
- This dialog does NOT report device settings for external sources.

**Copy Active** Available ONLY when there is a conflict which causes at least one channel to be Blocked. When clicked, the mechanical device settings of the **Active** channel are copied to the Blocked channels. A warning message appears to remind you that power to one or more channels may be increased. **Exception:** When one or more Noise channels are present, then the settings of the two Noise switches are be determined by the lowest-numbered Noise channel if none are the active channel.

**Trigger** Launches the Trigger dialog box.

**OK** Closes the dialog box.

**Cancel** Does not apply changes that were made, and closes the dialog box.
Power Limit and Power Offset

- Overview
- How to access Power Limit and Power Offset settings

Other System Topics

Overview

Power Limit (Global scope)

Global power limit sets a maximum source power level for individual test ports. This value limits port power for all channels and all applications. Power levels that attempt to exceed the power limit is clipped at the limit.

Notes

- The power limit can NOT be set for power levels which are below the power level that is required by the analyzer to achieve phase lock - approximately -30 dBm.

- Because Fast Sweep mode allows power spiking, it is NOT allowed when a power limit is enabled.

- Components that are added to the RF path are accounted for by entering their loss (negative) or gain (positive) in the Power Offset section of the dialog box.

- VNA Applications may change RF path components. For example, IMD for Converters may change the combiner path and add an amplifier for LO input. Compensation is NOT made for these changes and port power may exceed the power limit or port power may be clipped unnecessarily.

- Power limiting does NOT clip power spikes that may occur during frequency band crossings.

- External test set ports are also included for power limiting.

Power Offset (Channel scope)

Power Offset provides a method of compensating port power for added attenuation or amplification in the source path. The result is that power at the specified port, all dialogs, and annotation, reflects the added components.
How to access the Offsets and Limits settings

Also accessed through the Preferences dialog.

Using **Hardkey/SoftTab/Softkey**

1. Press **Power > Leveling & Offsets > Offsets and Limits...**

Using a mouse

1. Click **Stimulus**
2. Select **Power**
3. Select **Offsets and Limits...**

**Offsets and Limits** dialog box help

Click a WHITE cell to change values. **Shaded cells** can NOT be changed.

Remote commands can be sent to lock and unlock the dialog box (UI) settings.

**Power Limit**

Limits the source power at each test port for ALL channels. Use this feature to protect DUTs that are sensitive to overpowered at the input. **Source Power** levels that exceed the **Limit** at the specified port are clipped at the limit, the power level in the **Source Power** column turns red, and an error message is displayed on the screen.

The Power Limit settings and **PLimit** status indicator survive Instrument Preset. When an Instrument State is recalled, the current Power Limit settings are applied to the recalled state.

To learn more, see **Power Limit Overview** (scroll up).

**State / Limit**

- **ON** - Power is limited to the adjacent value at the specified source port and displays **PLimit** in the status bar indicating that a power limit is ON.
• **OFF** - Power is NOT limited to this value, but to the maximum power of the source.

For VNA models with a second internal source, the **Port 1 Src2** Power Limit setting is NEVER available. Make the setting at the standard **Port 1**.

**Power Offset**

Power Offset provides a method of compensating port power for added attenuation or amplification in the source path. The result is that power at the specified port, all dialogs, and annotation reflects the added components.

- For amplification, use positive offset.
- For attenuation, use negative offset.

**Important Note:** Power Offset is added AUTOMATICALLY when a **Source Power Calibration**, **Guided Power Cal**, or **Power Compensation** is ON with Fixture Embed/Deembed. If you are NOT seeing the correct power level at your DUT, view the power Offset column in this dialog for unexpected offsets.

Optionally change the Source Power or Port Power values so that the following equation reflects your requirement:

\[
\text{Source Power} + \text{Power Offset} = \text{Port Power}
\]

**Source Cal  ON / OFF**

**Notes**

- Power Offset can be used with **Power Sweeps**. When a power sweep is enabled, the Start and Stop power levels are reported in this dialog.

- When port power offsets are used, port powers are automatically **uncoupled**. Port powers may not be coupled again until all port offsets are zero.

- **Cal All** does not automatically use the specified power offset during a calibration. To use a power offset for one or more ports when performing a **Cal All**, you must set the power offset value in the **Cal All** wizard.

**OK**  Closes the dialog box.
Receiver Temperature

This feature allows you to read the current temperature on the receiver microcircuit.

This feature is available on ALL models except the N523x models and the 4-port N5244A and N5245A models with DSP Version 4. Also, this feature is not available on the E5080A.

- To read temperature, press System > Service > Diagnostics > Receiver Temperature....
- The temperature reading is updated with every sweep.
- Temperature is available in Celsius and Fahrenheit.
- Temperature can also be read using remote commands.
  - SCPI: SENSE:TEMPerature?
  - COM: ReceiverTemperature
Setting System Impedance

The system impedance can be changed for measuring devices with an impedance other than 50 ohms, such as waveguide devices. The VNA mathematically transforms and displays the measurement data as though the VNA ports were the specified impedance value. Physically, the test ports are always about 50 ohms.

How to change the System Impedance

Using **Hardkey/SoftTab/Softkey**

1. Press **Scale > Constants > System Z0**

**System Z0 softtab help**

Allows you to change the system impedance (default setting is 50 ohms).

**Z0** Displays the current system impedance.

**For 75 ohm devices:**

1. Change the system Z0 to 75 ohms.
2. Connect minimum loss pads (75 ohm impedance) between the analyzer and the DUT to minimize the physical mismatch.
3. Perform a calibration with 75 ohm calibration standards.

**For waveguide devices**

When selecting a Cal Kit with an impedance other than 50 ohms (Waveguide = 1 ohm), it is **NO LONGER NECESSARY** to change the System Impedance setting before performing a calibration. The impedance for the calibration is now derived from the Cal Kit 'Connector' impedance setting.
The following links require an Internet connection.

Network Analyzer Basics

This self-paced webinar discusses the basic concepts of Network Analysis.

From the Internet: Network Analyzer Basics.
Protection against electrostatic discharge (ESD) is essential while removing or connecting cables to the network analyzer. Static electricity can build up on your body and can easily damage sensitive internal circuit elements when discharged. Static discharges too small to be felt can cause permanent damage. To prevent damage to the instrument:

- **Always** have a grounded, conductive table mat in front of your test equipment.
- **Always** wear a grounded wrist strap, connected to a grounded conductive table mat, having a 1 MΩ resistor in series with it, when making test setup connections.
- **Always** wear a heel strap when working in an area with a conductive floor. If you are uncertain about the conductivity of your floor, wear a heel strap.
- **Always** ground yourself before you clean, inspect, or make a connection to a static-sensitive device or test port. You can, for example, grasp the grounded outer shell of the test port or cable connector briefly.
- **Always** ground the center conductor of a test cable before making a connection to the analyzer test port or other static-sensitive device. This can be done as follows:
  1. Connect a short (from your calibration kit) to one end of the cable to short the center conductor to the outer conductor.
  2. While wearing a grounded wrist strap, grasp the outer shell of the cable connector.
  3. Connect the other end of the cable to the test port and remove the short from the cable.

See [Analyzer Accessories](#) for ESD part numbers.
Absolute Output Power

An absolute output-power measurement displays absolute power versus frequency.

- What is Absolute Output Power?
- Why Measure Absolute Output Power?
- Accuracy Considerations
- How to Measure Absolute Output Power

See other Amplifier Parameters topics

What is Absolute Output Power?

An absolute-output power measurement displays the power present at the analyzer's input port. This power is absolute—it is not referenced (ratioed) to the incident or source power. In the log mag format, values associated with the grid's vertical axis are in units of dBm, which is the power measured in reference to 1 mW.

- 0 dBm = 1 mW
- -10 dBm = 100 μW
- +10 dBm = 10 mW

In the linear mag format, values associated with the grid's vertical axis are in units of watts (W).

Why Measure Absolute Output Power?

Absolute output power is measured when the amplifier's output must be quantified as absolute power rather than a ratioed relative power measurement. For example, during a gain compression measurement, it is typical to also measure absolute output power. This shows the absolute power out of the amplifier where 1-dB compression occurs.

Accuracy Considerations

The output power of the amplifier should be sufficiently attenuated if necessary. Too much output power could:
Damage the analyzer receiver

- Exceed the input compression level of the analyzer receiver, resulting in inaccurate measurements.

Attenuation of the amplifier's output power can be accomplished using either attenuators or couplers.

The amplifier may respond very differently at various temperatures. The tests should be done when the amplifier is at the desired operating temperature.

How to Measure Absolute Power

Do the following to measure absolute output power:

1. Preset the analyzer.

2. Select an unratioed power measurement (receiver B). Learn how.

3. Set the analyzer's source power to 0 dBm.

4. Select an external attenuator (if needed) so the amplifier's output power will be sufficiently attenuated to avoid causing receiver compression or damage to the analyzer's port-2.

5. Connect the amplifier as shown in the following graphic, and provide the dc bias.

6. Select the analyzer settings for your amplifier under test.

7. Remove the amplifier and connect the measurement ports together. Store the data to memory. Be sure to include the attenuator and cables in the test setup if they will be used when measuring the amplifier.

8. Save the instrument state to memory.

9. Reconnect the amplifier.

10. Select the data math function Data/Memory.
11. Scale the displayed measurement for optimum viewing and use a marker to measure the absolute output-power at a desired frequency.

12. Print or save the data to a disk.
Active Probing with the VNA

You can use passive and active, single and differential probes with the VNA.

RF Probes are available from Keysight, including the U1818A/B active probe with a maximum frequency of 12 GHz. Learn more at the Keysight website.

**Note: The VNA does NOT have a probe power port.**

Therefore, order the U1818A/B with banana plugs (Opt 002) for powering with an external power supply, such as the Keysight E3620A Dual Output Power Supply or equivalent.

See Also

- App Note 5990-4387EN: High Frequency Probing Solutions for Time and Frequency Domain Applications.
- U1818A/B Technical Overview

Procedure

Use the following general procedure to make VNA measurements with ONE U1818B active probe:

1. Connect the U1818A/B banana plugs to an external power supply. Power requirements for the U1818A/B are +15V (at 42mA) and -12.6V (at 12 mA).
2. Connect the U1818A/B to the VNA port 2 directly, or using an adapter or short cable.

3. Connect your DUT input connector to the VNA port 1 directly, or using an adapter or short cable.

4. On the VNA, press **Preset**.

5. Press **Meas > S-Param > S21** (transmission measurement).

6. Press **Freq**, then select the Start and Stop frequency range of the measurement. The maximum frequency of the U1818B is 12 GHz.

7. Connect the probe tips as close as possible to the DUT input connector (point A in the above image).

   **Note:** The probe tip has two pins:
   
   - One pin is connected to the signal trace.
   - The other pin is connected to the ground trace.

8. Press **Cal > Other Cals > Smart Cal...**

   - This calibration removes the losses (from the VNA test ports to the DUT) from subsequent measurements. Learn more about VNA calibration.
   
   - When correctly calibrated, the S21 measurement should show a flat response at 0 dB across the frequency range.
   
   - Connect the probe tips anywhere in the DUT path to view the frequency response between the DUT input and the probe tips.
   
   - To view the response in Time Domain, press **Math > Time Domain > Transform**. Learn about Time Domain measurements.
The AM-PM conversion of an amplifier is a measure of the amount of undesired deviation (PM) that is caused by amplitude variations (AM) inherent in the system.

- What Is AM-PM Conversion?
- Why Measure AM-PM Conversion
- Accuracy Considerations
- How to Measure AM-PM Conversion

What Is AM-PM Conversion?

AM-to-PM conversion measures the amount of undesired phase deviation (PM) that is caused by amplitude variations (AM) of the system. For example, unwanted phase deviation (PM) in a communications system can be caused by:

**Unintentional amplitude variations (AM)**

- Power supply ripple
- Thermal drift
- Multipath fading

**Intentional modulation of signal amplitude**

- QAM
- Burst modulation

AM-to-PM conversion is usually defined as the change in output phase for a 1-dB increment in the power-sweep applied to the amplifier's input (i.e. at the 1 dB gain compression point). It is expressed in degrees-per-dB (°/dB). An ideal amplifier would have no interaction between its phase response and the power level of the input signal.
Why Measure AM-PM Conversion

AM-to-PM conversion is a critical parameter in systems where phase (angular) modulation is used, such as:

- FM
- QPSK
- 16QAM

It is a critical parameter because undesired phase deviation (PM) causes analog signal degradation, or increased bit-error rates (BER) in digital communication systems. While it is easy to measure the BER of a digital communication system, this measurement alone does not help you understand the underlying causes of bit errors. AM-to-PM conversion is one of the fundamental contributors to BER, and therefore it is important to quantify this parameter in communication systems.

Refer to the I/Q diagram below for the following discussion on how AM-to-PM conversion can cause bit errors.
The desirable state change is from the small solid vector to the large solid vector.

With AM-to-PM conversion, the large vector may actually end up as shown with the dotted line. This is due to phase shift that results from a change in the input power level.

For a 64QAM signal as shown (only one quadrant is drawn), we see that the noise circles that surround each state would actually overlap, which means that statistically, some bit errors would occur.

**Accuracy Considerations**

With this method of measuring AM-to-PM conversion, the modulation frequency is approximately the inverse of the sweep time. Even with the fastest power sweep available on most network analyzers, the modulation frequency ends up being fairly low (typically less than 10 Hz). This could cause a slight temperature change as the sweep progresses, especially if the amplifier has low thermal mass, typical of an unpackaged device. Results using this method could differ slightly if the nonlinear behavior of an amplifier is extremely sensitive to thermal changes.

- The amplifier may respond very differently at various temperatures. The tests should be done when the amplifier is at the desired operating temperature.

- The output power of the amplifier should be sufficiently attenuated if necessary. Too much output power could:
  - damage the analyzer receiver
  - exceed the input compression level of the analyzer receiver, resulting in inaccurate measurements

- Attenuation of the amplifier's output power can be accomplished using:
  - Attenuators
  - Couplers
The frequency-response effects of the attenuators and couplers must be accounted for during calibration since they are part of the test system. Proper error-correction techniques can reduce these effects.

The frequency response is the dominant error in an AM-to-PM conversion measurement setup. Performing a thru-response measurement calibration significantly reduces this error. For greater accuracy, perform a 2-port measurement calibration.

How to Measure AM-PM Conversion

1. Preset the analyzer.

2. Select an S21 measurement in the power-sweep mode.

3. Enter the start and stop power levels for the analyzer's power sweep. The start power level should be in the linear region of the amplifier's response (typically 10-dB below the 1-dB compression point). The stop power should be in the compression region of the amplifier's response.

4. Select an external attenuator (if needed) so the amplifier's output power will be sufficiently attenuated to avoid causing receiver compression or damage to the analyzer's port 2.

5. Connect the amplifier as shown in the following graphic, and provide the dc bias.

6. Select the analyzer settings for your amplifier under test in order to perform a swept-power gain compression measurement at a chosen frequency. See Gain Compression.

7. Remove the amplifier and perform a measurement calibration. Be sure to include the attenuator and cables in the calibration setup if they will be used when measuring the amplifier.

8. Save the instrument state to memory.

9. Reconnect the amplifier.

10. Use a reference marker to target the amplifier's input power at the 1-dB gain compression point. Select a second marker and adjust its stimulus value until its response is 1-dB below the reference marker.
11. Change the S21 measurement from a log magnitude format to a phase format (no new calibration is required).

12. Find the phase change between the markers. The value is the AM-to-PM conversion coefficient at the 1-dB gain compression point.

13. Print the data or save it to a disk.

Gain

\[ t = \frac{V_{\text{trans}}}{V_{\text{inc}}} \]

Gain (dB) = -20\log_{10}|t|

Gain (dB) = P_{\text{out}} (dBm) - P_{\text{in}} (dBm)

The ratio of the amplifier's output power (delivered to a Z0 load) to the input power (delivered from a Z0 source). Z0 is the characteristic impedance, in this case, 50Ω.

For small signal levels, the output power of the amplifier is proportional to the input power. Small signal gain is the gain in this linear region.

As the input power level increases and the amplifier approaches saturation, the output power reaches a limit and the gain drops. Large signal gain is the gain in this nonlinear region. See Gain Compression.
Gain Flatness

The variation of the gain over the frequency range of the amplifier. See Small Signal Gain and Flatness.

Reverse Isolation

The measure of transmission from output to input. Similar to the gain measurement except the signal stimulus is applied to the output of the amplifier. See Reverse Isolation.

Gain Drift versus Time (temperature, bias)

The maximum variation of gain as a function of time, with all other parameters held constant. Gain drift is also observed with respect to other parameter changes such as temperature, humidity or bias voltage.

Deviation from Linear Phase

The amount of variation from a linear phase shift. Ideally, the phase shift through an amplifier is a linear function of frequency. See Deviation from Linear Phase.

Group Delay

\[ \tau_g(\infty) = -\frac{\Delta \phi}{\Delta \omega} \]

\[ = -\frac{1}{360} \times \frac{\Delta \phi}{\Delta f} \]

The measure of the transit time through the amplifier as a function of frequency. A perfectly linear phase shift would have a constant rate of change with respect to frequency, yielding a constant group delay. See Group Delay.

Return Loss (SWR, \( \rho \))

\[ \Gamma = \frac{V_{\text{refl}}}{V_{\text{inc}}} = \rho \angle \phi \]

Reflection coefficient = \( \rho \)

Return loss (dB) = \(-20 \log_{10} \rho \)

\[ \text{SWR} = \frac{1+\rho}{1-\rho} \]

The measure of the reflection mismatch at the input or output of the amplifier relative to the system \( Z_0 \).
characteristic impedance.

**Complex Impedance**

\[
Z = \frac{1 + \Gamma}{1 - \Gamma} \ast Z_0 \\
= -R + jX
\]

Complex impedance (1+G). The amount of reflected energy from an amplifier is directly related to its impedance. Complex impedance consists of both a resistive and a reactive component. It is derived from the characteristic impedance of the system and the reflection coefficient. See [Complex Impedance](#).

**Gain Compression**

See [Gain Compression Application](#).

**AM-to-PM Conversion Coefficient**

\[
\frac{\Delta \Phi}{\Delta P} = \frac{\Delta \theta}{\Delta P}
\]

The amount of phase change generated in the output signal of an amplifier as a result of an amplitude change of the input signal.

The AM-to-PM conversion coefficient is expressed in units of degrees/dB at a given power level (usually P1dB, which is the 1 dB gain compression point). See [AM-PM Conversion](#).
Antenna Measurements

This topic describes how to setup a Keysight Vector Network Analyzer (VNA) to make S21 measurements on an array of antennas. Measurements can be made on up to 100 antenna arrays (Ports) and up to 15 discrete frequencies.

Measurement Sequence

1. The VNA is set to a start frequency.
2. As the antenna moves, the VNA responds to each external trigger signal by measuring an antenna port.
3. When all ports are measured, the VNA increments to the next frequency.
4. Again the VNA measures all ports, and so forth until all ports are measured at all frequencies in the forward direction.
5. As the antenna begins moving in the opposite direction, the same sequence occurs, except the VNA decrements in frequency until all ports are measured at all frequencies and the VNA is set back to the original start frequency.

Once setup, only external trigger signals are sent to the VNA. After each trigger, measurement data is stored in internal VNA memory.

How to set up the VNA

1. Press Preset
2. Press Trigger > Main > Trigger Source > External
3. Press Trigger > Main > Trigger
4. In the Trigger dialog under Trigger Scope, select Channel
5. Click OK

Forward Sweep

1. Press Trace > Trace N > Trace N to add a new trace.
2. Press Trace > Trace Setup > Measure....
3. Select S21 then Channel Number 1
4. Press **Trigger > Main > Trigger**

5. In the Trigger dialog under **Channel Trigger State**, set the Trigger Mode to **Point**

6. Click **OK**

7. Press **Sweep > Main > Sweep Type > Segment Sweep**

8. Click **OK**

9. Press **Sweep > Segment Table > Insert Segment**

10. Do this 15 times

11. For each Segment in the Segment table:

   1. Click **State:** and select **ON**
   2. Click both **START** and **STOP** Frequency: (each new segment ascends in frequency)
   3. Click **Points:** type Number of Ports (elements)

**Reverse sweep**

Repeat the following steps for each frequency: (up to 15)

- Increment the channel number (**X**) Starting with Channel 2
- Decrement the frequency (**F**)

1. Press **Trace > Trace N > Trace N** to add a new trace.

2. Press **Trace > Trace Setup > Measure....**

3. Click **S21** then Channel Number **X**

4. When a window contains four traces, press **Trace > Trace Setup > Add Trace > New Trace + Window.**

5. Click **OK**

6. Press **Trigger > Main > Trigger**

7. In the Trigger dialog under **Channel Trigger State**, set the Trigger Mode to **Point**

8. Click **OK**

9. Press **Sweep > Main > Sweep Type > Segment Sweep**
10. Click **OK**

11. Press **Sweep > Segment Table**

12. In the Segment table

   1. Click **State**: and select **ON**
   
   2. Click both **START** and **STOP** Frequency $F$
   
   3. Click **Points**: type Number of Ports (elements)
Balanced Measurements

- How the analyzer makes Balanced Measurements

Other Measurement Setup Topics

Check out the Integrated True Mode Stimulus Application (iTMSA).

What are Balanced Devices?

Standard Single-ended devices generally have one input port and one output port. Signals on the input and output ports are referenced to ground.

Balanced devices have two pins on either the input, the output, or both. The signal of interest is the difference and average of the two input or output lines, not referenced to ground.
Differential and Common Modes Model

On balanced devices, the signal of interest is the **difference** and **average** of the two input or output lines. In balanced device terminology, these signals are known as the Differential and Common modes.

The following model shows how two signals (A and B) combine to create Differential and Common mode signals:

- **Signal A** is fixed at 1V peak
- **Signal B** is selectable
- **Differential** is calculated as **A minus B**
- **Common** is calculated as the **AVERAGE of A and B**

**Note:** Click **Signal B** selections to see various Differential and Common signals.

<table>
<thead>
<tr>
<th>Signal A</th>
<th>Calculations</th>
<th>Differential (A - B)</th>
<th>Common (Avg) (A + B) / 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1V</td>
<td>1 - 0 = 1</td>
<td>(1 + 0)/2 = .5</td>
<td></td>
</tr>
<tr>
<td>180° Out of Phase</td>
<td>1V</td>
<td>1 - (-1) = 2</td>
<td>(1 + (-1))/2 = 0</td>
</tr>
<tr>
<td>180° Out of Phase</td>
<td>2V</td>
<td>1 - (-2) = 3</td>
<td>(1 + (-2))/2 = -.5</td>
</tr>
<tr>
<td>In Phase</td>
<td>1V</td>
<td>1 - 1 = 0</td>
<td>(1 + 1)/2 = 1</td>
</tr>
<tr>
<td>In Phase</td>
<td>2V</td>
<td>1 - 2 = -1</td>
<td>(1 + 2)/2 = 1.5</td>
</tr>
</tbody>
</table>

**Notes:**

- Even when Signal B is 0V, like a Single-ended signal, there is still a unique Differential and Common mode representation of the two individual signals.
- The above model does not show a DUT. The difference and average of two signals can be calculated for
both the balanced INPUT and balanced OUTPUT of a device.

**Measuring Mixed Mode (Balanced) S-Parameters**

Mixed mode S-parameters combine traditional S-parameter notation with balanced measurement terminology.

Some balanced devices are designed to amplify the differential component and reject the common component. This allows noise that is common to both inputs to be virtually eliminated from the output. For example, a balanced device may amplify the differential signal by a factor of 5, and attenuate the common signal by a factor of 5. Using traditional S-parameter notation, an S21 is a ratio measurement of the device **Output** / device **Input**. Mixing this with balanced terminology, we could view the amplifier's Differential Output signal / Differential Input signal. To see this parameter on the analyzer, we would select an Sdd21 measurement using the following balanced notation:

\[ \text{Sabxy} \]

Where

- **a** - device output mode
- **b** - device input mode

**Measuring Imbalance Parameters**

Imbalance is a measure of how well two physical ports that make up a balanced port are matched. With a perfectly balanced port, the same amount of energy flows to both ports and the magnitude of the ratio...
of these ports is 1.

The notation is similar to traditional S-parameters. In the following diagrams, the letters a, b, c, and d are used because any analyzer port can be assigned to any logical port using the port mapping process.

For example, in the following single-ended - balanced formula, Sba indicates the device output port is logical port b and the input port is logical port a.
Imbalance parameter when measuring a balanced - single-ended device.

\[ \text{Imbal} = \frac{\text{Scb}}{\text{Sca}} \]

Imbalance1 and Imbalance2 parameters when measuring a balanced - balanced device.

\[ \text{Imbal}_1 = \frac{\text{Sac} - \text{Sad}}{\text{Sbc} - \text{Sbd}} \]
\[ \text{Imbal}_2 = \frac{\text{Sca} - \text{Scb}}{\text{Sda} - \text{Sdb}} \]
Imbalance1 and Imbalance2 parameters when measuring a **single-ended - single-ended - balanced** device.

![Diagram of DUT ports and imbalance equations]

**Measuring CMRR (Common Mode Rejection Ratio)**

CMRR is a ratio of the transmission characteristic in differential mode over the transmission characteristic in the common mode of the balanced port as the measurement parameter. A high value indicates more rejection of common mode, which is desirable in a device that transmits information in the differential portion of the signal. The table below shows the CMRR parameter you can select when measuring each balanced device.

**Device Topology and Port Mapping**

As we have seen on balanced inputs and outputs, the signal of interest is the difference or average of two BALANCED input or BALANCED output lines. It is also possible to have single-ended ports
AND balanced ports on the same device. The two balanced input or output lines are referred to as a single "logical" port.

When configuring a balanced measurement on the analyzer, select a device 'topology'. Then map each test port to the DUT ports. The analyzer assigns "logical ports". See how to set device topology.

The following device topologies can be measured by a 4-port analyzer.

- **Balanced / Balanced**
  (2 logical ports - 4 physical ports)

- **Single-ended / Balanced**
  (2 logical ports - 3 physical ports)
These topologies can be used in the reverse (⇐⇒) direction to measure:

- **Balanced / Single-ended** topology
- **Balanced / Single-ended - Single-ended** topology

For example, to measure a **Balanced / Single-ended** topology, measure the S12 (reverse direction) of a **Single-ended / Balanced** topology.

**Calibrating Balanced Measurements**

Balanced measurements are calibrated in the same manner as single-ended (standard) measurements. However, for highest accuracy, you must choose Thru paths so that each transmission path of the balanced measurement is represented. For a Balanced/Balanced topology, this means that FOUR Thru connections should be made.

For example (see following image):

---

![Diagram of Balanced / Single-ended topology](image)

![Diagram of Single-ended - Single-ended / Balanced topology](image)
- Balanced Port 1 is ports 1 and 3
- Balanced Port 2 is ports 2 and 4
- Thru paths to be calibrated should be: 12, 14, 32, 34.
- Paths 13, and 24 are less important.

To select Thru paths:

1. From SmartCal, on the Select DUT Connectors and Cal Kits page, check **Modify Cal**.
2. Click **Next** to see the following Cal Wizard page:

![Modify Cal](image)

**How the analyzer makes Balanced Measurements**

When using standard Balanced measurements, the analyzer does not provide true balanced measurements by stimulating both balanced inputs together and measuring both outputs relative to one another. Instead, the analyzer makes only Single-ended measurements. On a Balanced/ Balanced device, it stimulates each input and measures each output individually. From the output data, the analyzer calculates the Differential and Common outputs from the DUT using the same math formulas as the above model. However, all measurements and calculations are performed in frequency domain using complex (magnitude and phase) data. The Balanced S-parameter display data is then calculated from the Differential and Common inputs and outputs.

In iTMSA, the VNA **DOES** stimulate both balanced inputs with true balanced sources.
Complex Impedance

When making an S₁₁ or S₂₂ measurement of your device under test, you can view complex-impedance data such as series resistance and reactance as well as phase and magnitude information. Complex impedance data can be viewed using either the Smith Chart format or the Polar format.

- What Is Complex Impedance?
- Accuracy Considerations
- How to Measure Complex Impedance

What Is Complex Impedance?

Complex-impedance data is information that can be determined from an S₁₁ or S₂₂ measurement of your device under test, such as:

- Resistance
- Reactance
- Phase
- Magnitude

The amount of power reflected from a device is directly related to the impedances of both the device and the measuring system. For example, the value of the complex reflection coefficient (Γ) is equal to 0 only when the device impedance and the system impedance are exactly the same (i.e. maximum power is transferred from the source to the load). Every value for Γ corresponds uniquely to a complex device impedance (as a function of frequency), according to the equation:

\[ Z_L = \frac{(1 + \Gamma)}{(1 - \Gamma)} \times Z_0 \]

where \( Z_L \) is your test device impedance and \( Z_0 \) is the measuring system's characteristic impedance.

Complex Impedance is best viewed using either Polar or Smith Chart format.

Accuracy Considerations

- The Smith chart is most easily understood when used with a full scale value of 1.0.
- For greater accuracy when using markers in the Smith chart or polar formats, activate the discrete marker mode.

- The uncertainty of reflection measurements is affected by:
  - Directivity
  - Reflection tracking
  - Source match
  - Load match (with 2-port devices)

With a 2-port calibration, the effects of these factors are reduced. A 1-port calibration provides the same accuracy if the output of the device is well terminated. Refer to the graphic below for the following discussion.

If you connect the device between both analyzer ports, it is recommended that you use a 10 dB pad on the output of the device to improve measurement accuracy. This is not necessary if you use a 2-port calibration since it corrects for load match.

If you connect a two-port device to only one analyzer port, it is recommended that you use a high-quality load (such as a calibration standard) on the output of the device.

How to Measure Complex Impedance

1. Connect the device as shown in the previous graphic.
2. Preset the analyzer.
3. Set up, calibrate, and perform an S11 or S22 measurement.
4. View impedance data:
   a. Select the Smith Chart format.
b. Scale the displayed measurement for optimum viewing.

c. Position the marker to read the resistive and reactive components of the complex impedance at any point along the trace.
d. Print the data or save it to a disk.

5. View the magnitude and phase of the reflection coefficient:

   a. Select the Smith chart format or the Polar format.
   
   b. Select either Lin Marker or Log Marker formats.
   
   c. Scale the displayed measurement for optimum viewing.
   
   d. Position the marker to read the frequency, magnitude, and phase of the reflection coefficient ($\Gamma$) at any point along the trace.
   
   e. Print the data or save it to a disk.
The VNA has three Delay functions which are similar but are used in different ways.

1. **Group Delay format** is used to display the Group Delay of a network. Group Delay is defined as:

   \[-d(\phi)/d(\omega)\]  
   -- where \(\phi\) is radian angle, and \(\omega\) is radian frequency.

   Since it is defined by a derivative, the value must be determined from an analytic function. However, the VNA makes discrete measurements, so we approximate the group delay by taking the finite difference:

   \[-(1/360) \cdot \delta(\phi)/\delta(f)\]  
   -- where \(\phi\) is degree angle and \(f\) is frequency in Hz. The 1/360 does the proper conversion of degrees to radians and Hz frequency to radian frequency.

   From this we can see that, if the phase response of a network varies with frequency, then the Group Delay must vary as well. In fact, many filters are specified by the variation of their Group Delay.

   If we measure the phase response of a lossless cable, it should be a straight line. But, of course, nothing is perfect. The phase response will have a small amount of noise. This is due to trace noise of the VNA, and the loss with real cables or transmission lines, which causes a small amount of non-linear phase change with frequency. So, if we look at the Group Delay of a cable, we will see a small amount of variation. Also, if the frequency spacing is small enough when you make the measurement, the \(\delta(f)\) in the denominator becomes very small, so the delay can have wide swings with just a little noise.

   To overcome this issue, we sometimes add smoothing to a phase trace, which widens the effective \(\delta(f)\), called the aperture, and provides a less noisy Group Delay response. The Group Delay of a device is only valid for a given frequency aperture. [Learn more about Group Delay.](#)

2. **Electrical Delay** function. On many filters, the passband response is specified for a maximum value of "Deviation from Linear Phase". When looking at the passband of a multi-pole filter, one sees the phase changing very rapidly. This makes it difficult to determine the linearity of the phase response. The Electrical Delay function subtracts out a "LINEAR PHASE" equivalent to the delay time value computed as above. When you use this function, you dial in the Linear Delay such that a CONSTANT PHASE SLOPE is removed from the phase trace, until the phase trace is mostly flat. The remaining variation is the deviation from linear phase.

   To make this task a little less tedious, the VNA has a marker function called Marker =>> Delay. This function computes the Group Delay value at the marker position, using a 20% smoothing aperture, then changes the Electrical Delay value to this value. Obviously, if the phase trace is not perfectly linear, moving the marker and recomputing the delay will result in different values. The phase slope added by
the electrical delay function applies only to the current measurement. That is, each measurement (S11, S22, S12, S21) can have its own value of electrical delay. Learn more about Deviation from Linear Phase.

3. **Port Extension** is a function that is similar to calibration. It applies to all the traces in a given channel. It compensates for the phase response change that occurs when the calibration reference plane is not the same as the measurement plane of the device.

Let's look at an example of a DUT that is mounted on a PCB fixture with SMA connectors. We can easily calibrate at the SMA connectors. But if we add the fixture to measure the board-mounted device, the apparent phase of the DUT is changed by the phase of the PCB fixture. We use port extensions to add a LINEAR PHASE (constant delay) to the calibration routines to shift the phase reference plane to that of the DUT. This is ONLY valid if the fixture consists of a transmission line with linear phase response, and this limitation is usually met in practice. The main reason that it is NOT met is that there is mismatch at the SMA-to-PCB interface. This mismatch was not removed with the error correction because it occurs AFTER the SMA connector. Ripple can be seen on the display as signals bounce back and forth between the mismatch and the DUT. If the DUT is well matched, the ripple effect is very small. However, when we use Automatic Port Extension (APE), and we leave the fixture open (the DUT removed), the reflection is large and we see larger ripples. That is why APE uses a curve fitting process to remove the effects of the ripple. For best effect, the wider the IF Bandwidth, the better we can "smooth-out" the ripples with curve fitting. Still, we are fitting a LINEAR PHASE SLOPE to the phase response, and thus we use only a single Port Extension Delay value to represent the phase slope.

The method used by older VNAs to get this same functionality was to add a mechanical line stretcher to the reference channel, which removed a fixed delay amount from the port. Port extensions give 1x the delay for transmission at each port, and 2x the delay for reflection, so it differs somewhat from Electrical Delay above, in that the math function depends upon the measurement being made. The signal passes twice through the fixture for reflection (out and back), but only once for each port on transmission. For S21, the phase slope added is the sum of the port 1 and port 2 Port Extension Delay values.

The "User Range" APE function is used in cases where a fixture has limited bandwidth, perhaps due to tuning elements or bias elements. In this case, the model of constant delay for the fixture over the whole bandwidth is not valid, so a narrower "User Range" of frequencies can be selected to compute the delay. Since the aperture is smaller, there is more uncertainty in the delay computation for port extension. Also, for those who had been using the Marker => Delay function to estimate the delay, we added the "Active Marker" selection to APE, which works exactly the same as Marker->Delay. Learn more about Automatic Port Extensions.
Deviation from Linear Phase

Deviation from linear phase is a measure of phase distortion. The electrical delay feature of the analyzer is used to remove the linear portion of the phase shift from the measurement. This results in a high-resolution display of the non-linear portion of the phase shift (deviation from linear phase).

- What Is Linear Phase Shift?
- What Is Deviation from Linear Phase?
- Why Measure Deviation from Linear Phase?
- Using Electrical Delay
- Accuracy Considerations

See also Comparing the Analyzer Delay Functions

See other Tutorials

What Is Linear Phase Shift?

Phase shift occurs because the wavelengths that occupy the electrical length of the device get shorter as the frequency of the incident signal increases. Linear phase-shift occurs when the phase response of a device is linearly proportional to frequency. Displayed on the analyzer, the phase-versus-frequency measurement trace of this ideal linear phase shift is a straight line. The slope is proportional to the electrical length of the device. Linear phase shift is necessary (along with a flat magnitude response) for distortionless transmission of signals.

What Is Deviation from Linear Phase?

In actual practice, many electrical or electronic devices will delay some frequencies more than others, creating non-linear phase-shift (distortion in signals consisting of multiple-frequency components). Measuring deviation from linear phase is a way to quantify this non-linear phase shift.

Since it is only the deviation from linear phase which causes phase distortion, it is desirable to remove the linear portion of the phase response from the measurement. This can be accomplished by using the electrical delay feature of the analyzer to mathematically cancel the electrical length of the device under test. What remains is the deviation from linear phase, or phase distortion.
Why Measure Deviation from Linear Phase?

The deviation from linear phase measurement accomplishes the following:

- Presents data in units of phase rather than units of seconds (group delay). For devices that pass modulated signals, units of phase may be most practical.
- Provides a less noisy measurement than a group delay measurement.

Using Electrical Delay

The electrical delay feature is the electronic version of the mechanical "line stretcher" of earlier analyzers. This feature does the following:

- Simulates a variable-length lossless transmission line, which is effectively added to or removed from the reference signal path.
- Compensates for the electrical length of the device under test.
- Flattens the measurement trace on the analyzer's display. This allows the trace to be viewed at high resolution in order to see the details of the phase nonlinearity.
- Provides a convenient method to view the deviation from linear phase of the device under test. See the following graphic.

Learn how to set Electrical Delay.

Accuracy Considerations

The frequency response of the test setup is the dominant error in a deviation from linear phase measurement. To reduce this error, perform a 2-port measurement calibration.

How to Measure Deviation from Linear Phase:

1. Preset the analyzer.
2. If your device under test is an amplifier, it may be necessary to adjust the analyzer's source power:

   - Set the analyzer's source power to be in the linear region of the amplifier's output response (typically 10-dB below the 1-dB compression point).
   - Select an external attenuator (if needed) so the amplifier's output power will be sufficiently attenuated to avoid causing receiver compression or damage to the analyzer's port 2.

3. Connect the device under test as shown in the following graphic.

4. Select an S21 measurement.

5. Select the settings for your device under test, including the following:

   - **Format**: phase
   - **Scale**: autoscale

6. Remove the device and perform a calibration.

7. Reconnect the device.

8. Scale the displayed measurement for optimum viewing.

9. Create a marker in the middle of the trace.

10. Press Marker > Marker -> Functions > Marker -> Delay to invoke the Marker to Electrical Delay function. This flattens the phase trace.

11. If desired, on the **Scale** menu, click Electrical Delay to fine-tune the flatness of the phase trace.

12. Use the markers to measure the maximum peak-to-peak deviation from linear phase.

13. Print the data or save it to a disk.
20 GHz Coupler Directivity Measurement Example

The purpose of this example is to show how to use the PNA Equation Editor to create a directivity measurement trace, in order to measure a directional coupler’s directivity easily. Two different methods, using measurement trace data formatted differently are explained below. Results are displayed on the bottom left and bottom right hand side windows of the PNA screen. It’s important to note that either approach produces the same end result, as shown with markers on both equation editor traces. Measurement trace selection and formatting are critical for making this work correctly. A user would only need to use one method or the other, but both ways are explained.

1. Set up the connections between the PNA and a directional coupler as shown below.

![Diagram of PNA and directional coupler connections]

   a. Connect PNA Port 1 to coupler's input port.
   b. Connect PNA Port 2 to coupler's output port.
   c. Connect PNA Port 3 to coupler's coupled port.

2. Set up basic stimulus conditions for directional coupler's measurement.

   a. Preset the PNA.
   b. Set start frequency to 1 GHz.
   c. Set stop frequency to 20 GHz.
   d. Set power level to the default value.
   e. Set IFBW to 30 Hz.
3. **Make window setup, trace measurement, and formatting selections.**

Establish four measurement windows on the display screen. Set up windows and traces such that the left-hand side will show traces 1, 2, and 3 in upper left window, as well as trace 7 in lower-left window. Corresponding to the DUT connection diagram, traces 1, 2, and 3 will be S21, S31, and S32 measurements, respectively; and all must be formatted as real. Trace 7, an equation editor trace, will be log magnitude formatted. Trace 7 will be a S11 trace when it is created, but it will be modified to be a directivity equation trace later.

For the right-hand side of the display screen, create traces 4, 5, and 6 in upper-right window, as well as trace 8 in lower right window. Traces 4, 5, and 6, will also be S21, S31, and S32 measurements, respectively, but these traces are formatted in linear magnitude. Trace 8, an equation editor trace, will need to be log magnitude formatted, just like the lower-left window for equation Trace 7. Trace 8 will be a S11 trace when it is created, but it will be modified to be a directivity equation trace later, too.

4. **Create the directivity traces for Tr 7 and Tr 8 with the equation editor.**

Tr 7 will use real formatted data from Tr 1, Tr2, and Tr3 in the equation.

   a. Select Tr 7.
   b. From the Marker/Analysis menu, select Analysis, then Equation Editor....
   c. Enter the Equation as Dir_from_REAL_Data=S32/(S31*S21).
   d. Check the Enable Equation box.
   e. Click on OK.

Tr 8 will use linear magnitude formatted data from Tr 4, Tr 5, and Tr 6 in the equation.

   a. Select Tr 8.
   b. From the Marker/Analysis menu, select Analysis, then Equation Editor....
   c. Enter the Equation as Dir_from_LinMag_Data=Tr6/(Tr5*Tr4).
   d. Check the Enable Equation box.
   e. Click on OK.

**Note:** Window titles were added to show user comments about the traces in each window. This is strictly optional, but if desired, window titles can be added by doing the following:

   a. Select the Response menu, then choose Display, Labels, then Window Title....
   b. In the Window Title dialog box, enter a meaningful title.
   c. Check the Enable box.
   d. Click on OK.
Note: To demonstrate the equivalent results of both equation editor methods for directivity measurements, marker tables were set up for Tr 7 and Tr 8 in windows 3 and 4, respectively. Again, this is optional, but recommended.

5. Perform a 3-port calibration.

Note: An N4433A-010 ECal module was used in this example.

6. Display directivity measurement results.

a. Initiate a single sweep.
b. Observe that Tr 7 and Tr 8 are the same.

Discussion

In linear terms, the textbook equation for calculating a coupler's directivity is:

Directivity = Isolation - (Coupling + Loss)

Using log rules, this equation becomes:
Directivity = Isolation / (Coupling * Loss)

The PNA equation editor has all the underlying data structures in complex real/imag (linear) values. All the math in the textbook is also in linear terms, so the equation needs to be Dir_from_LinMag_Data=Tr6/(Tr5*Tr4). That equation was implemented in Tr 8.

The equation editor also returns the complex data structure in real/imag, so to get directivity in dB, set the format to log magnitude for Tr 7 - just like Tr 8. (And the equation is complex, so phase will be preserved for directivity too, so you can think of this as directivity_re_im.)

For Tr 8 (in dB), the correct directivity is for isolation – (coupling + loss). But since you cannot form this equation in equation editor, you have to use the complex form. So you can refer to Tr 6, but the reference is to the last complex result, not to the formatted trace.

This equation, Directivity_LogM=20*log(mag(S32/(S31*S21)), while correct (and not used in this example), will result in the complex value being formed in dB (you are formatting in the equation editor), so you would need to set the format to real to see the dB value, oddly enough. So, it is best to use Dir=S32/(S31*S21) and set the format as desired (e.g. Logmag) to get directivity in dB.
Filter Measurements

The main filter measurements discussed in this topic include:

- **Measurements**
  - Bandwidth
  - Center Frequency
  - Q Factor
  - Filter Loss (Insertion Loss)
  - Retrieving Filter Statistics
- **Ripple**
  - Retrieving Peak to Peak Ripple
- **Smoothing**
  - Performing a Smoothing Function
- **Related SCPI and COM Remote Commands**

![Diagram of bandwidth measurement](image)

**Bandwidth**

Marker search functions automatically determine the bandwidth of a band-pass filter by placing a marker on the maximum level (marker 1), a marker on the lower frequency (marker 2), and a marker on the higher frequency (marker 3). The higher and lower frequencies are determined by specifying a target bandwidth level. The default target bandwidth level is -3 dB which means that the bandwidth of a band-pass filter is determined by measuring the higher and lower frequencies at -3 dB below the peak.

To find the bandwidth of a notch filter, a positive value would be entered for the target bandwidth level (for example, 3 dB). For notch filters, the marker search functions place a marker on the minimum
level (marker 1), a marker on the lower frequency (marker 2), and a marker on the higher frequency (marker 3).

Center Frequency

In addition to being used to determine the bandwidth, markers 2 and 3 are used to determine the center frequency of a band-pass or notch filter by calculating the mathematical midpoint between them as shown in the diagram above.

Q Factor

After determining the bandwidth and center frequency using the marker search functions, the VNA also calculates the Q factor as the ratio of Center Frequency to Bandwidth (Center Frequency / Bandwidth).

The VNA can measure very high Q factors limited only by the IF bandwidth and the number of sampling points. You must ensure that a sufficient number of sampling points are utilized for accurate results.

Filter Loss (Insertion Loss)

The filter loss is the loss caused by the insertion of the filter into the transmission line. The loss is defined as follows:

\[ 20 \log_{10} |S_{21}| \]

Marker search functions retrieve the filter loss as the Y-axis value of marker 4. This is the loss of the filter at its center frequency.

Retrieving Filter Statistics

The following procedure retrieves filter bandwidth, center frequency, loss, and Q factor.

1. Press Search > Bandwidth & Notch > BW Level.

2. Enter the target bandwidth level (default is -3 dB).

Note: To find the bandwidth of a notch filter, enter a positive value for the target bandwidth level.
4. Press **Search > Bandwidth & Notch > Bandwidth Search** to retrieve filter statistics.

Ripple

Ripple refers to the amplitude deviation of the band-pass filter, which is also referred to as filter flatness. The VNA's trace statistics functions are used to find the peak to peak ripple in the band-pass as shown in **Retrieving Peak to Peak Ripple**.

![Ripple diagram](image)

**Retrieving Peak to Peak Ripple**

The following procedure sets up and retrieves the ripple of the filter.

1. Press **Math > Analysis > Statistics....**
2. In the **Trace Statistics** dialog, select **Statistics - Mean, Standard Deviation, Peak to Peak**.
3. In the pull-down menu, select a **User** number to assign a range.
4. Enter the **Start** and **Stop** frequencies for the ripple measurement. This should be the bandwidth of the band-pass filter.
5. Click **OK** to retrieve the peak to peak ripple of the filter.

Smoothing
The VNA has a smoothing function that applies an average smoothing on a trace. The smoothing function is defined as follows:

\[ Y_{n_{_\text{Smooth}}} = \frac{[Y(n-m) + Y(n-m+1) + \cdots + Y(n) + \cdots Y(n+m-1) + Y(n+m)]}{2m+1} \]

where \(2m + 1\) is called the smoothing aperture measured in points.

The smoothing function is also provided as a percentage of the span and then converted to smoothing points as follows:

\[ m = \text{int} \left[ \frac{N \cdot (\text{smoothing percent})}{2} \right] \]

When applied, each point becomes an average of the surrounding points.

**Performing a Smoothing Function**

1. Press `Avg BW > Smoothing > Smoothing ON`.
2. If entering a percentage of the span, press `Avg BW > Smoothing > Smooth Percent` which will change the number of Smoothing Points appropriately.
3. If entering smoothing points, press `Avg BW > Smoothing > Smooth Points` which will change the Smoothing Percent Span appropriately.

Small Signal Gain and Flatness

Small signal gain is the gain in the amplifier's linear region of operation. This is typically measured at a constant input power over a swept frequency. Gain flatness is the measure of the variation of gain over a specified frequency range.

- What Is Gain?
- What Is Flatness?
- Why Measure Gain and Flatness?
- Accuracy Considerations
- How to Measure Gain and Flatness

What Is Gain?

RF amplifier gain is defined as the difference in power between the amplifier output signal and the input signal. It is assumed that both input and output impedances of the amplifier are the same as the characteristic impedance of the system.

- Gain is called S21 using S-parameter terminology
- Gain is expressed in dB—a logarithmic ratio of the output power relative to the input power.
- Gain can be calculated by subtracting the input from the output levels when both are expressed in dBm, which is power relative to 1 milliwatt.
- Amplifier gain is most commonly specified as a minimum value over a specified frequency range. Some amplifiers specify both minimum and maximum gain, to ensure that subsequent stages in a system are not under or over driven.

What Is Flatness?

Flatness specifies how much the amplifier's gain can vary over the specified frequency range. Variations in the flatness of the amplifier's gain can cause distortion of signals passing through the amplifier.
Why Measure Small-Signal Gain and Flatness?

Deviations in gain over the bandwidth of interest will induce distortion in the transmitted signal because frequency components are not amplified equally. Small-signal gain allows you to quantify the amplifier's gain at a particular frequency in a 50-ohm system. Flatness allows you to view the deviations in the amplifier's gain over a specified frequency range in a 50-ohm system.

Accuracy Considerations

- The amplifier may respond very differently at various temperatures. The tests should be done when the amplifier is at the desired operating temperature.
- The output power of the amplifier should be sufficiently attenuated if necessary. Too much output power could:
  - damage the analyzer receiver
  - exceed the input compression level of the analyzer receiver, resulting in inaccurate measurements.

Attenuation of the amplifier's output power can be accomplished using:

  - attenuators
  - couplers

The frequency-response effects and mismatches of the attenuators and couplers must be accounted for during calibration since they are part of the test system. Proper error-correction techniques can reduce these effects.

- The frequency response is the dominant error in a small-signal gain and flatness measurement setup. Performing a thru-response measurement calibration significantly reduces this error. For greater accuracy, perform a 2-port measurement calibration.
- Reducing IF bandwidth or using averaging improves measurement dynamic range and accuracy, at the expense of measurement speed.

How to Measure Gain and Flatness

1. Preset the analyzer.
2. Select an S21 measurement parameter.
3. Set the analyzer's source power to be in the linear region of the amplifier's output response (typically 10-dB below the 1-dB compression point).
4. Select an external attenuator (if needed) so the amplifier's output power will be sufficiently attenuated to avoid causing receiver compression or damage to the analyzer's port-2.

5. Connect the amplifier as shown in the following graphic, and provide the dc bias.

6. Select the analyzer settings for your amplifier under test.

7. Remove the amplifier and perform a measurement calibration. Be sure to include the attenuator and cables in the calibration setup if they will be used when measuring the amplifier.

8. Save the instrument-state to memory.

9. Reconnect the amplifier.

10. Scale the displayed measurement for optimum viewing and use a marker to measure the small signal gain at a desired frequency.

11. Measure the gain flatness over a frequency range by using markers to view the peak-to-peak ripple.

12. Print or save the data to a disk.
Gain compression measures the level of input power applied to an amplifier that will cause a distorted output.

The Gain Compression Application (Opt S93086A/B) makes fast and accurate compression measurements.

- What Is Gain Compression?
- Why Measure Gain Compression?
- Accuracy Considerations
- How to Measure Gain Compression

What Is Gain Compression?

Gain compression occurs when the input power of an amplifier is increased to a level that reduces the gain of the amplifier and causes a nonlinear increase in output power.

The analyzer has the ability to do power sweeps as well as frequency sweeps. Power sweeps help characterize the nonlinear performance of an amplifier. Refer to the graphic below (a plot of an amplifier's output power versus input power at a single frequency) for the following discussion.

- The amplifier has a linear region of operation where gain is constant and independent of power level. The gain in this region is commonly referred to as "small-signal gain."
- As the input power increases, the amplifier gain appears to decrease, and the amplifier goes into compression.
- The most common measurement of amplifier compression is the 1-dB compression point. This is defined as
the input power (or sometimes the output power) which results in a 1-dB decrease in amplifier gain (relative to the amplifier's small-signal gain).

Why Measure Gain Compression?

When driven with a sinusoid, the output of an amplifier is no longer sinusoidal in the compression region. Some of the amplifier output appears in harmonics, rather than occurring only at the fundamental frequency of the input signal.

As input power is increased even more, the amplifier becomes saturated, and output power remains constant. At this point, further increases in amplifier input power result in no change in output power.

In some cases (such as with TWT amplifiers), output power actually decreases with further increases in input power after saturation, which means the amplifier has negative gain.

Since gain is desired in amplifier operation, it is important to know the limit of input signal that will result in gain compression.

Accuracy Considerations

The network analyzer must provide sufficient power to drive the amplifier into saturation. If you need a higher input-power level than the source of the analyzer can provide, use a preamplifier to boost the power level prior to the amplifier under test. (See High Power PNA-X.) If using a preamplifier, you can increase measurement accuracy in the following ways:

- Use a coupler on the output of the preamplifier so that a portion of the boosted input signal can be used for the analyzer's reference channel. This configuration removes the preamplifier's frequency response and drift errors from the measurement (by ratioing).
- Perform a thru-response calibration including the preamplifier, couplers, and attenuators in the test setup.

The output power of the amplifier should be sufficiently attenuated if necessary. Too much output power could:

- Damage the analyzer receiver
- Exceed the input compression level of the analyzer receiver

Attenuation of the amplifier's output power can be accomplished using:

- Attenuators
- Couplers
The frequency-response effects of the attenuators and couplers must be considered during calibration since they are part of the test system. Proper error-correction techniques can reduce these effects.

- The frequency response is the dominant error in a gain compression measurement setup. Performing a thru-response measurement calibration significantly reduces this error.
- The amplifier may respond very differently at various temperatures. The tests should be done when the amplifier is at the desired operating temperature.
- Reducing IF bandwidth or using measurement averages improves accuracy, at the expense of measurement speed.

How to Measure Gain Compression

This procedure shows you how to make the following three measurements used to determine amplifier gain compression:

1. A Swept-Frequency Gain Compression measurement locates the lowest frequency at which the 1-dB gain compression first occurs.

2. A Swept-Power Gain Compression measurement shows the input power at which a in a 1-dB drop in gain occurs as a power ramp is applied to the amplifier at a particular frequency point (found in measurement 1).

3. An Absolute Power measurement shows the absolute power out (in dBm) at compression.

Swept-Frequency Gain Compression Measurement

A measurement of swept frequency gain compression locates the frequency point where 1-dB compression first occurs.

1. Preset the analyzer.

2. Select an S21 measurement parameter.

3. Set the analyzer's source power to be in the linear region of the amplifier's output response (typically 10-dB below the 1-dB compression point).

4. Select an external attenuator (if needed) so the amplifier's output power will be sufficiently attenuated to avoid causing receiver compression or damage to the analyzer's port-2.

5. Connect the amplifier as shown in the following graphic, and provide the dc bias.

6. Select the analyzer settings for your amplifier under test. To reduce the effects of noise, you may want to specify a narrower IF bandwidth.
7. Remove the amplifier and perform a thru-response calibration. Be sure to include the attenuator and cables in the calibration setup if they will be used when measuring the amplifier.

8. Save the instrument-state to memory.

9. Reconnect the amplifier.

10. Position a marker at approximately mid-span.

11. Adjust the analyzer's scale to 1 dB per division.

12. Store the trace in memory and display Data/Mem.

13. Gradually increase the source power until a 1-dB decrease in gain is observed at the first frequency over some portion of the trace.

14. Use markers to locate the frequency where the 1-dB decrease in gain first occurs. Note this frequency for use in the following measurement.

15. Print the data or save it to a disk.

---

**Swept-Power Gain Compression Measurement**

A swept-power gain compression measurement shows the input power resulting in a 1-dB drop in gain as a power ramp at a particular frequency (found in step 13 of the previous measurement) is applied to the amplifier.

1. If not already done, perform the previous measurement of swept-frequency gain compression.

2. Setup an S21 measurement in the power-sweep mode. Include the following settings:

   - Set the CW frequency to the frequency noted in step 14 of the previous measurement of swept-frequency gain compression.
Enter the start and stop power levels for the sweep. The start power should be in the linear region of the amplifier’s response (typically 10 dB below the 1-dB compression point). The stop power should be in the compression region of the amplifier’s response.

3. Adjust the scale to 1-dB per division.

4. Use markers (including reference marker) to find the input power where the 1-dB decrease in gain occurs.

5. Print the data or save it to a disk.

**Absolute Output Power Measurement**

An absolute-power measurement shows the absolute power-out (in dBm) of the amplifier at compression.

1. Select an unratioed (absolute) power measurement. Choose the B input if using the test setup in the previous graphic.

2. Retain the CW frequency used in the previous measurement of swept-power gain compression.

3. Set a marker to the input power level where the 1-dB decrease in gain occurs (found in step 4 of the previous measurement).

4. Scale the displayed measurement for optimum viewing.

5. Read the marker value to find the absolute output power of the amplifier (in dBm) where the 1-dB decrease in gain occurs.

6. Print the data or save it to a disk.

**Note:** The measurement calibration does not apply to absolute power. Therefore, if there is any attenuation external to the analyzer, you will have to correct for it manually.
Gated Measurement

- Measurement Description
- Quick Setup
- Complete Measurement Setup

See All Spectrum Analyzer Examples

Measurement Description

Gated spectrum analyzer (SA) measurements (requires option S93090xA) use triggering to capture data during the active trigger state only and thus ensure that the response more closely represents the device response. Learn more.

This example shows how to set up a gated SA measurement using an external or internal pulse to trigger the receiver measurement and an internal pulse to trigger the RF source. In order to pulse the VNA RF source with an internal pulse, option S93025A/B is required. This option is not required in the case of an external RF source with pulsed capabilities.

Note: Internal Pulse0 pulse generator is not suitable for gated SA because the pulse width cannot be set. Instead, use Pulse3 as shown in this topic (pulse 1 to pulse 4 would work too, but without the direct Trigger source to Pulse3 internal connection).

Quick Setup

Many of the setup steps can be performed automatically if option S93026A/B is installed. The quick setup will configure a gated SA measurement using internal pulse generators and modulators. The RBW will be set to the maximum setting that is compatible with the pulse width. If minor adjustments are required after performing the quick setup, refer to the Complete Measurement Setup.

1. Press Meas > S-Param > Meas Class....
2. Select Spectrum Analyzer, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.
3. Press Freq > Main > SA Setup... and set the frequency of the VNA source.
4. Set the source Power to the desired level.
5. Click on the Pulse Setup... button, select Standard Pulse, then ensure that the Pulse Width is much
smaller than the Pulse Period then click OK.

![Image of Pulse Setup](image)

Complete Measurement Setup

1. If using an external pulse generator, connect a cable from the pulse generator output to the **Meas Trig In BNC** on the rear panel of the VNA.
2. On the VNA front panel, press **Meas > S-Param > Meas Class**....
3. Select **Spectrum Analysis**, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.
4. Press **Freq > Main > SA Setup...** and set the frequency of the VNA source.
5. Click on the Advanced tab then click on the Advanced >> button.
6. Click on the Trigger tab then click on the Trigger button.
7. Click on the Meas Trigger tab and select **Meas Trig In BNC** (if using an external pulse generator) or **Pulse3** (if using internal pulse3 to Meas Trig In bypass) under **Source** and **High Level** under **Level/Edge**.

Selecting **High Level** (or **Low Level**) under **Level/Edge** triggers LO acquisitions and continues to acquire data while the pulse trigger remains high (or low).

**Note:** Edge triggering does not perform gated measurements.
7. Click on the **Setup** tab and select **External (uses Pulse3)** (if using internal pulse3 to Meas Trig In bypass) or **External (uses MEAS TRIG IN)** (if using an external pulse generator),

8. Select **Channel** under **Trigger Scope, Point** for the **Trigger Mode**, then click **OK**.

For gated SA measurements, **Point** does not refer to a data point or display point. Instead, it refers to the next LO acquisition. For SA, each time the LO is shifted an acquisition is captured. The time for each LO acquisition is based on the **ADC Record Size** times the ADC Sampling Frequency (10 nsec). The number of LO acquisitions is determined by the **Image Reject** setting. This information is displayed in the SA Setup dialog in the Advanced tab.
9. Click on the **Source** tab and set the source **Power** to the desired level.

10. Click on the **Power and Attenuator...** button, set the **Leveling Mode** to **Open Loop**, then click **OK**.

**Open Loop** leveling is used during pulse conditions with the internal source modulator. No leveling is used in setting the source power. Learn more.

11. In the **Trigger** tab, click on the **Pulse Gen Config** button.
11. If using an internal pulse generator and an internal RF source, perform the following steps:
   a. Set the pulse **Frequency**.
   b. Enable **Pulse1** and set the **Width** greater than the acquisition time (displayed in the Advanced tab).
      Pulse1 is the RF source trigger.
   c. Ensure that **Enable Source 1 Modulator** is checked, and that **Pulse1** is enabled and selected as the **Modulator Drive**.
   d. If using the internal Pulse3 bypass, enable **Pulse3** and set the **Width** greater than the acquisition time per LO (displayed in the Advanced tab).
   e. Click **OK**.

12. If using an external pulsed generator as the measurement trigger, perform the following steps:
   a. Ensure that the pulse width is greater than the acquisition time per LO (displayed in the Advanced tab).
   b. Connect the RF source pulse trigger output to the VNA **Meas Trig In BNC** connector on the rear panel.
Group delay is a measure of phase distortion. Group delay is the actual transit time of a signal through a device under test as a function of frequency. When specifying group delay, it is important to specify the aperture used for the measurement.

- What is Group Delay?
- Group Delay versus Deviation from Linear Phase
- What Is Aperture?
- Accuracy Considerations
- How to Measure Group Delay

See also Comparing the Delay Functions.

**See other Amplifier Parameter topics**

**What Is Group Delay?**

Group delay is:

- A measure of device phase distortion.
- The transit time of a signal through a device versus frequency.
- The derivative of the device’s phase characteristic with respect to frequency.

Refer to the graphic below for the following discussion:
The phase characteristic of a device typically consists of both linear and higher order (deviations from linear) phase-shift components.

<table>
<thead>
<tr>
<th>Linear phase-shift component:</th>
<th>Higher-order phase-shift component:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Represents average signal transit time.</td>
<td>Represents variations in transit time for different frequencies.</td>
</tr>
<tr>
<td>Attributed to electrical length of test device.</td>
<td>Source of signal distortion.</td>
</tr>
</tbody>
</table>

Refer to the graphic below for the following discussion:

In a group delay measurement:

- The linear phase shift component is converted to a constant value (representing the average delay).
- The higher order phase shift component is transformed into deviations from constant group delay (or group delay ripple).
- The deviations in group delay cause signal distortion, just as deviations from linear phase cause distortion.
- The measurement trace depicts the amount of time it takes for each frequency to travel through the device under test.

Refer to the following equation for this discussion on how group delay is calculated:
Phase data is used to find the phase change \((-d\phi)\).

- A specified frequency aperture is used to find the frequency change \((d\omega)\).
- Using the two values above, an approximation is calculated for the rate of change of phase with frequency.
- This approximation represents group delay in seconds (assuming linear phase change over the specified frequency aperture).

**Group Delay versus Deviation from Linear Phase**

Group delay is often a more accurate indication of phase distortion than **Deviation from Linear Phase**.

**Deviation from linear phase** results are shown in the upper region of the following graphic: Device 1 and device 2 have the same value, despite different appearances.

**Group Delay** results are shown in the lower region: Device 1 and device 2 have different values of group delay. This is because in determining group delay, the analyzer calculates slope of phase ripple, which is dependent on number of ripples which occur per unit of frequency.

**What Is Aperture?**

During a group delay measurement, phase is measured at two closely spaced frequencies and then computes the phase slope. The frequency interval (frequency delta) between the two phase measurement points is called the aperture. Changing the aperture can result in different values of group delay.
delay. The computed slope (-delta phase / delta frequency) varies as the aperture is increased. This is why when you are comparing group delay data, you must know the aperture that was used to make the measurements.

Refer to the graphic below for the following discussion:

<table>
<thead>
<tr>
<th>Narrow aperture:</th>
<th>Wide aperture:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provides more detail in phase linearity.</td>
<td>Provides less detail in phase linearity because some phase response averaged-out or not measured.</td>
</tr>
<tr>
<td>Makes measurement susceptible to noise (smaller signal-to-noise ratio) and phase detector resolution.</td>
<td>Makes measurement less susceptible to noise (larger signal-to-noise ratio).</td>
</tr>
</tbody>
</table>

Group delay measurements can be made using the following sweep types:

- Linear frequency

- List frequency sweep segment - The group delay aperture varies depending on the frequency spacing and point density. Therefore the aperture is not constant in segment sweep. In segment sweep, extra frequency points can be defined to ensure the desired aperture.

**How to set Group Delay Aperture**

**Using Hardkey/SoftTab/Softkey**

1. Press **Format > Format 1 > Group Delay Aperture...**

**Using a mouse**

1. Click **Response**
2. Select **Format**
3. Select **Group Delay Aperture**
Group Delay Aperture dialog box help

Although the Group Delay Aperture is defined as the difference in frequency between two data points (see What Is Aperture?), the group delay calculation can be averaged over many adjacent data points, similar to the smoothing feature. The number of adjacent data points can be set using any of the following methods:

**Note:** You can change the default Group Delay Aperture to two points using a Preference. Learn how.

**Points**  
Number of adjacent data points to average. Default setting is 11 points. Choose a value between 2 and the current number of points in the channel.

**Percent of Span**  
The data points within this percentage of the current frequency span are averaged. Choose a value between (2 points / current number of points) and 100 percent. The span must contain at least two data points.

**Frequency**  
The data points within this frequency range are averaged. The frequency range must contain at least two data points.

When the frequency span or number of points is reduced so that the current Group Delay Aperture is NOT attainable, the Aperture is adjusted to the new frequency span or number of points.

**OK**  
Applies setting changes and closes the dialog box.

**Cancel**  
Closes the dialog. Setting changes are NOT applied.

Accuracy Considerations

It is important to keep the phase difference between two adjacent measurement points less than 180° (see the following graphic). Otherwise, incorrect phase and delay information may result. Undersampling may occur when measuring devices with long electrical length. You can verify that the phase difference measured between two adjacent points is less than 180° by adjusting the following settings until the measurement trace no longer changes:

- Increase the number of points
- Narrow the frequency span

Electrical delay may also be used to compensate for this effect.
The frequency response is the dominant error in a group delay test setup. Performing a thru-response measurement calibration significantly reduces this error. For greater accuracy, perform a 2-port measurement calibration.

Particularly for an amplifier, the response may vary differently at various temperatures. The tests should be done when the amplifier is at the desired operating temperature.

**How to Measure Group Delay**

1. Preset the analyzer.

2. If your DUT is an amplifier, it may be necessary to adjust the source power:
   - Set the source power to be in the linear region of the amplifier’s output response, typically 10 dB below the 1 dB compression point.
   - If needed, use an external attenuator so the amplifier output power will be sufficiently attenuated to avoid causing receiver compression or damage to test port 2.

3. Connect the DUT as shown in the following graphic.
4. Select an S21 measurement.

5. Select the settings for your DUT:
   - frequency range
   - number of measurement points.
   - format: delay
   - scale: autoscale

6. Remove the DUT and perform a measurement calibration.

7. Reconnect the DUT.

8. Scale the displayed measurement for optimum viewing.

9. Use the Group Delay Aperture setting to increase the aperture, reducing noise on the trace while maintaining meaningful detail.

10. Use the markers to measure group delay (expressed in seconds) at a particular frequency of interest.

11. Print the data or save it to a disk.
High-Gain Amplifier Measurements

When measuring High-Gain Amplifiers, errors in measuring any of the S-parameters during calibration can result in error in the S21 measurement. This is because all the S-parameters are used in the error correction math.

A particular problem occurs with high gain amplifiers because the source power is set very low. Thus, when making reverse measurements (S22, S12) the signal-to-noise is poor and the raw measurements can be dominated by noise. This noise in the raw measurements will result in a noisy trace appearing for corrected S21 or S11.

If you are using a large attenuator on port 2 (which improves output match), perform an Enhanced Response Calibration as follows. This corrects for the same errors as the full 2-port correction EXCEPT the interaction between the raw load match and the DUT output match.

1. There is NO need to Uncouple the port powers.
2. Set port powers to an acceptable level. Do NOT overpower the test port.
3. Perform Enhanced Response Cal. Learn how. (Does not measure or correct for S12 or S22 port match).

If you want to do a full correction (for example, when your amplifier output match is poor so the Enhanced Response Cal above is not adequate), then...

1. Uncouple the port powers. Learn how.
2. Set input (port 1) power to approximately the output power of the amplifier up to 0 dBm
3. Set reverse (port 2) power to the same power (for measuring isolation and S22)
4. Perform a Full 2-port Cal.
5. Re-set the input power (port 1) to a lower power level appropriate for driving the amplifier.
Additional Error due to Mismatch of DUT Output Match and Raw Load Match
High-Power Amplifier Measurements with the VNA

The following is a block diagram of all models of the PNA-X Opt 423. However, all of the models listed below have the same or fewer components.

The configuration displayed here is used to make high power amplifier measurements using a preamplifier at the rear panel. The preamplifier can then be switched (SW1) as needed using the RF Configurator.

</table>

**ALL Switches:** Damage level = 1 Watt (+30 dBm) while switching.

**ALL Step Attenuators:** Damage level = 1 Watt (+30 dBm) while switching.

**Notes**

**At J11** (rear-panel), max power is 4 dB to 11 dB higher than Source 1 Out at front panel jumper due to loss of the coupler thru arms, bias-tees, and cables.

**At J10** max power +33 dBm, which is the damage level of the bridge. With +30 dBm into J10, there will be about +15 dBm at R1, assuming 15 dB coupling factor for the R1 bridge. +15 dBm is the damage level of that receiver. Therefore, it may be necessary to add attenuation in place of the R1 loop, not only to protect the receiver, but to bring it out of compression. The 0.1 dB compression level spec for the R1 receiver is between -3 and -18 dBm, depending on the frequency and option configuration.

**At Test Port 2** (DUT output): With the bias-tees (orange), only +30 dBm is allowed into the test port. With Opt 222/422 (bias-tees removed), +43 dBm is allowed. Add appropriate attenuation to not damage other components.

**About the PNA-X Option 222/422**

Option 222 and 422 are designed to permit insertion of high power amplifiers and other signal conditioning equipment to allow high power network measurements at RF levels up to 20 Watts (+43 dBm) from 10 MHz to 26.5 GHz. These options supply extended power range attenuators without bias tees. This is similar to the PNA-X -219 (add extended power range and bias-tees to 2-Port analyzer) or PNA-X -419 (add extended power range and bias-tees to 4-Port analyzer) but deletes the bias tees from the test set.

Noise Power Ratio (NPR) Measurement

In this topic:

- Requirements
- Measurement Description
- Physical Setup
- NPR Measurement Procedure
- Calibrate Modulation

Requirements

- Spectrum Analyzer Option S93090xA/B
- 2- or 4-Port PNA with ability to connect an external modulated source
- Supported external sources:
  - E8267D PSG Vector Signal Generator
  - M8190A with E8267D PSG Vector Signal Generator
  - M9383A MCS (wideband vector, 44 GHz, with enhanced phase noise)
  - N5182B MXG RF Vector Signal Generator
  - N5192A and N5194A UXG Vector Adapter

See All Spectrum Analyzer Examples

Measurement Description

NPR measures the nonlinear behavior of an RF microwave amplifier under a modulated signal stimulus.

In this example, a setup file consisting of a multi-tone signal with a "notch" is created, uploaded to a signal generator, then fed into the VNA to test the behavior of the device. The "notch" refers to a small part of the frequency axis (up to 10% of the frequency span) that is forced to 0 (no signal) creating a notch in the power spectral density.
NPR is the sum of all intermodulation products across the pass band ratioed with the sum of all intermodulation products in the notch.

**Physical Setup**

The following diagram shows a typical hardware setup using an M8190A with a E8267D PSG with the signal connected to the VNA rear-panel Port 1 J10 input connector.

**NPR Measurement Procedure**

1. Connect the equipment as shown above.
2. On the PNA front panel, press **Preset**.
3. On the VNA front panel, press **Meas > S-Param > Meas Class...**.
4. Select **Spectrum Analysis**, then either:
   - **OK** delete the existing measurement, or
   - **New Channel** to create the measurement in a new channel.
5. The **SA Setup** dialog will be displayed.
6. Click on the **Source** tab. The **Source** dialog will be displayed.

7. If you need to add an external source, click on the **External Devices...** button. Learn more. After adding an external source, it should be listed in the **Name** column. The following is an example showing a modulation...
source called MXG. If the external source does not have modulation capabilities, the IQMod column will be grayed out.

</tbody>
</table>

8. Click on the Path Configuration... button and ensure that the correct RF path is selected according to the Physical Setup then click OK. For this example, the Combiner path for Port 1 is selected since the modulated signal is connected to the rear-panel J10 connector.

9. Click in the State field of your external source to change the state to ON.

10. Click in the Frequency field of your external source to change the frequency.

11. Click in the Power field of your external source to change the power.

12. Ensure that the appropriate reference receiver (signal at input of DUT) or test port receiver (signal at output of DUT) is selected based on the Physical Setup.
13. Click in the **IQMod** column for your external source and select **Edit** (refer to step 7 dialog example above) to access the **Modulation settings** dialog.

14. Click on the **Create/Edit Mod File...** button to access the **Create Modulation** dialog.
15. Click on the **Source Name** drop-down menu to select the source connected to the VNA that will be used to generate the modulated test signal.

16. Enter the span of the modulation signal in the **Signal Span** field.

17. Enter the tone spacing for the multi-tone signal in the **Tone Spacing** field.

18. The **Number of Tones** corresponds to the span and tone spacing. This value will be calculated when you click on the **Calculate** button.

19. Enter the span of the notch in the **Notch1 Span** field. The notch can be up to 10% of the span.

20. In the **Notch Location** drop-down menu, select **Symmetric** to position the notch in the center.

21. Click on the **Calculate** button to view the signal.

22. When the signal setup is complete, click on the **Save...** button to save this setup to a *.mdx file.

23. Click on the **OK** button to return to the **Modulation settings** dialog. The file path and name are displayed in the **Modulation Filename** field.
24. Check the **Enable Modulation** check box.

25. The **Autoset Frequencies and Coherence for current modulation** and **Autoset Markers** for the current modulation are checked by default. These options automatically adjust the spectrum analyzer frequency and spectrum analyzer markers each time adjustments are made to the modulation settings.

26. Click on the **OK** button to close the dialog. The following is an example signal:
Markers

The \( ? \) marker displays the notch frequency relative to the center frequency. In this example the notch is in the center so the frequency is 0 Hz. Also displayed is the notch marker power level.

The \( > R \) marker displays the center frequency (16 GHz) and the signal span (1.5 GHz).

The Band Power displays the total power within the signal span.

The Tone(1.40 GHz) displays the average tone power across the 1.5 GHz signal span minus the average tone power across the notch (1.5 GHz - 100 MHz = 1.4 GHz).

To learn more about these markers, refer to SA Analysis Markers.
27. To view the signal at the output of the DUT, add a new trace and select the B test port receiver since the output of the DUT is connected to port 2.

![Image of New Trace window]

28. The following is an example. The blue trace is the signal at the output of the DUT.
Calibrate Modulation

The Modulation Cal procedure optimizes the signal across the pass band and the depth of the notch.

1. Click on the **SA Setup...** button to open the **SA Setup** dialog then select the **Source** tab.

2. Click in the **IQMod** column for your external source and select **Edit** to access the **Modulation settings** dialog.
3. Click on the **Calibrate Modulation...** button. The **Modulation Cal - Setup** dialog is displayed.

4. Select **Power** to calibrate power across the entire pass band.

5. Select **Flatness** to calibrate flatness across the entire pass band.

6. Select **NPR Notch** to create as deep a notch as possible.

7. Under **Calibrate At**, select **Rcvr R1** for **Power Cal**, **Flatness Cal**, and **NPR Notch Cal**. This will perform a calibration at the input of the DUT.

8. The default values for **Max Nmbr Iterations** and **Desired Tolerance** will be used.

9. Click **Next**. The following dialog is displayed.
10. Click **Calibrate** to begin the calibration. When finished, the corrected modulated signal is displayed.
11. Click on the **Finish** button then click on the **Save & Exit** button to save the file. If one or more of the default tolerance values could not be achieved, a warning message is displayed. You have the option to change the tolerance values and re-calibrate or save the current calibration.

12. In the **Modulation Cal - Measure** dialog, note that the failed calibration is indicated in the text box.
13. In the **Modulation settings** dialog, **Enable Modulation Correction** is automatically checked if the user exits the wizard with **Exit & Save Cal**.

14. Click **OK**.

15. The following shows an optimized input signal.
We can now see the Power Amplifier DUT output NPR (blue trace -14.90 dB) and still monitor the NPR at the DUT input (yellow trace -27.61 dB here).
Phase Measurements

Knowledge of both magnitude and phase characteristics is needed for successful higher-level component integration.

- What are Phase Measurements?
- Why Measure Phase?
- Using the Analyzer's Phase Format
- Types of Phase Measurements

What are Phase Measurements?

Phase measurements are made using S-parameters, just like amplitude measurements. A phase measurement is a relative (ratio) measurement and not an absolute measurement. Phase measurements compare the phase of the signal going into a device (the incident signal) to the phase of the device's response signal. The response signal can be either reflected or transmitted. Assuming an accurate calibration has been performed, the difference in phase between the two signals (known as phase shift) is a result of the electrical characteristics of the device under test.

The following graphic shows the phase shift (in time or degrees) between an incident signal and a transmitted signal (as might be seen on an oscilloscope display).

Why Measure Phase?

Measuring phase is a critical element of network analysis. The following graphic lists five reasons for measuring both magnitude and phase.
When used in communications systems to pass signals, components or circuits must not cause excessive signal distortion. This distortion can be:

- Linear, where flat magnitude and linear phase shift versus frequency is not maintained over the bandwidth of interest.
- Nonlinear, such as AM-to-PM conversion.

It is important to measure how reflective a component or circuit is, to ensure that it transmits or absorbs energy efficiently. Measuring the complex impedance of an antenna is a good example.

**Using the Analyzer's Phase Format**

The analyzer's phase format displays a phase-versus-frequency or phase-versus-power measurement. The analyzer does not display more than ±180 degrees phase difference between the reference and test signals. As the phase value varies between +180 degrees and -180 degrees, the analyzer display creates the sawtooth pattern as shown in the following graphic.

The sawtooth pattern does not always reach +180 degrees and -180 degrees. This is because the measurement is made at discrete frequencies, and the data point at +180 degrees and -180 degrees may not be measured for the selected sweep.
Types of Phase Measurements

- **Complex impedance** data is information such as resistance, reactance, phase, and magnitude that can be determined from an S11 or S22 measurement. Complex impedance data can be viewed using either the Smith Chart format or the Polar format.

- **AM-to-PM conversion** is a measure of the amount of undesired phase deviation (PM) that is caused by amplitude variations (AM) of the system. AM-to-PM conversion is usually defined as the change in output phase for a 1-dB increment in the input power to an amplifier (i.e. at the 1 dB gain compression point). This is expressed in degrees-per-dB (°/dB).

- **Deviation from linear phase** is a measure of phase distortion caused by a device. Ideally, the phase shift through a device is a linear function of frequency. The amount of variation from this theoretical phase shift is known as its deviation from linear phase (also called phase linearity).

- **Group delay** is another way to look at phase distortion caused by a device. Group delay is a measure of transit time through a device at a particular frequency. The analyzer computes group delay from the derivative of the measured phase response.

**Deviation from Linear Phase Versus Group Delay**

Although deviation from linear phase and group delay are similar measurements, they each have their purpose.

The following are the advantages of deviation from linear phase measurements:

- Less noisy than group delay.
- Able to characterize devices that pass phase modulated signals, and show units of phase rather than units of seconds.

The following are the advantages of group delay measurements:

- More easily interpreted indication of phase distortion than deviation from linear phase.
- Able to most accurately characterize a device under test. This is because in determining group delay, the analyzer calculates the slope of the phase ripple, which is dependent on the number of ripples which occur per unit of frequency. Comparing two phase responses with equal peak-to-peak phase ripple, the response with the larger phase slope results in:
  - More group delay variation.
  - More signal distortion.
Reverse isolation is a measure of how well a signal applied to the device output is "isolated" from its input.

- What is Reverse Isolation
- Why Measure Reverse Isolation?
- Accuracy Considerations
- How to Measure Reverse Isolation

What is Reverse Isolation?

Reverse isolation is a measure of how well a signal applied to the device output is "isolated" from its input.

The measurement of reverse isolation is similar to that of forward gain, except:

- The stimulus signal is applied to the amplifier's output port.
- The response is measured at the amplifier's input port.

The equivalent S-parameter is S12.

Why Measure Reverse Isolation?

An ideal amplifier would have infinite reverse isolation-no signal would be transmitted from the output back to the input. However, reflected signals can pass through the amplifier in the reverse direction. This unwanted reverse transmission can cause the reflected signals to interfere with the desired fundamental signal flowing in the forward direction. Therefore, reverse isolation is important to quantify.

Accuracy Considerations

Since amplifiers often exhibit high loss in the reverse direction, generally there is no need for any attenuation that may have been used to protect the port 2 receiver during forward transmission measurements. Removing the attenuation will:
Increase the dynamic range, resulting in improved measurement accuracy.

Require a new calibration for maximum accuracy.

The RF source power can be increased to provide more dynamic range and accuracy.

**Note:** With the attenuation removed and the RF source power increased, a forward sweep could damage the analyzer's port 2 receiver. Do not perform a forward sweep or use 2-port calibration unless the forward power is set low enough to avoid causing port 2 receiver compression or damage.

If the isolation of the amplifier under test is very large, the transmitted signal level may be near the noise floor or crosstalk level of the receiver. To lower the noise floor:

- Use or increase measurement averages.
- Reduce the IF bandwidth of the analyzer.

**Note:** Reducing IF bandwidth or using averaging improves measurement dynamic range and accuracy, at the expense of reduced measurement speed.

- When crosstalk levels affect the measurement accuracy, reduce the crosstalk error term by performing a response and isolation calibration. When performing the isolation part of the calibration it is important to use the same average factor and IF bandwidth during the calibration and measurement.
- The frequency response of the test setup is the dominant error in a reverse isolation measurement. Performing a thru-response measurement calibration significantly reduces this error. This calibration can be done as part of the response and isolation calibration.
- The amplifier may respond very differently at various temperatures. The tests should be done when the amplifier is at the desired operating temperature.

**How to Measure Reverse Isolation**

1. Connect the amplifier as shown in the following graphic.
2. Preset the analyzer.

3. Select an S12 measurement.

4. Select the settings for your amplifier under test.

5. Remove the amplifier and perform a thru-response calibration or a response and isolation calibration.

6. Scale the displayed measurement for optimum viewing and use a marker to measure the reverse isolation at a desired frequency.

7. Print or save the data to a disk.
Reflection Measurements

Reflection measurements are an important part of network analysis.

- What are Reflection Measurements?
- Why Make Reflection Measurements?
- Expressing Reflected Waves
  - Return Loss
  - VSWR
  - Reflection Coefficient
  - Impedance
  - Summary of Expressions

What are Reflection Measurements?

To understand reflection measurements, it is helpful to think of traveling waves along a transmission line in terms of a lightwave analogy. We can imagine incident light striking some optical component like a clear lens. Some of the light is reflected off the surface of the lens, but most of the light continues on through the lens. If the lens had mirrored surfaces, then most of the light would be reflected and little or none would be transmitted.

1. Incident  2. Reflected  3. Transmitted

With RF energy, reflections occur when the impedance of two mated devices are not the same. A reflection measurement is the ratio of the reflected signal to the incident signal. Network analyzers measure the incident wave with the R (for reference) channel and the reflected wave with the A channel. Therefore, reflection is often shown as the ratio of A over R (A/R). We can completely quantify the reflection characteristics of our device under test (DUT) with the amplitude and phase
information available at both the A and R channel. In S-parameter terminology, S11 is a reflection measurement of port 1 of the device (the input port); S22 is a reflection measurement of the port 2 (the output port).

### Why Make Reflection Measurements?

One reason we make reflection measurements to assure efficient transfer of RF power. We do this because:

1. RF energy is not cheap. When energy is reflected, that means less energy is transmitted to where it is intended to go.

2. If the reflected energy is large, it can damage components, like amplifiers.

For example, in the following graphic, the radio station on the left is not operating at peak efficiency. The amplifier impedance is not the same as the transmission line, and the transmission line impedance is not the same as the antenna. Both of these conditions cause high reflected power. This condition results in less transmitted power, and the high reflected power could damage the amplifier.

![Reflection Measurement Diagram](image)

The radio station on the right installed properly "matched" transmission line and antenna. Very little of the transmitted signal is reflected, resulting in increased broadcast power, more listeners, more advertising revenue, and more profit. The amplifier, transmission, and antenna all need to be measured to ensure that reflected power is minimized.

### Expressing Reflected Waves

After making a reflection measurement, the reflection data can be expressed in a number of ways, depending on what you are trying to learn. The various expressions are all calculated by the analyzer from the same reflection measurement data. Each method of expressing reflection data can be graphically displayed in one or more formats. For more information, see display formats.

#### Return Loss

The easiest way to convey reflection data is return loss. Return loss is expressed in dB, and is a scalar (amplitude only) quantity. Return loss can be thought of as the absolute value or dB that the reflected signal is below the incident signal. Return loss varies between infinity for a perfect impedance match.
and 0 dB for an open or short circuit, or a lossless reactance. For example, using the log magnitude format on the analyzer, the measured reflection value on the screen may be -18dB. The minus sign is ignored when expressing return loss, so the component is said to have 18dB of return loss.

**VSWR**

Two waves traveling in opposite directions on the same transmission line cause a "standing wave". This condition can be measured in terms of the voltage standing wave ratio (VSWR or SWR for short). VSWR is defined as the maximum reflected voltage over the minimum reflected voltage at a given frequency. VSWR is a scalar (amplitude only) quantity. VSWR varies between one for a perfect match, and infinity for an open or short circuit or lossless reactance.

**Reflection Coefficient**

Another way of expressing reflection measurements is reflection coefficient gamma (\(\Gamma\)). Gamma includes both magnitude and phase.

The magnitude portion of gamma is called rho (\(\rho\)). Reflection coefficient is the ratio of the reflected signal voltage to the incident signal voltage. The range of possible values for \(\rho\) is between zero and one. A transmission line terminated in its characteristic impedance will have all energy transferred to the load; zero energy will be reflected and \(\rho = 0\). When a transmission line terminated in a short or open circuit, all energy is reflected and \(\rho = 1\). The value of rho is unitless.

Now for the phase information. At high frequencies, where the wavelength of the signal is smaller than the length of conductors, reflections are best thought of as waves moving in the opposite direction of the incident waves. The incident and reflected waves combine to produce a single "standing" wave with voltage that varies with position along the transmission line.

When a transmission line is terminated in its characteristic impedance (Zo) there is no reflected signal. All of the incident signal is transferred to the load, as shown in the following graphic. There is energy flowing in one direction along the transmission line.

When a transmission line is terminated in a short circuit termination, all of the energy is reflected back to the source. The reflected wave is equal in magnitude to the incident wave (\(\rho = 1\)). The voltage across any short circuit is zero volts. Therefore, the voltage of the reflected wave will be 180 degrees out of phase with the incident wave, canceling the voltage at the load.
When a transmission line is terminated in an open circuit termination, all of the energy is reflected back to the source. The reflected wave is equal in magnitude to the incident wave ($\rho = 1$). However, no current can flow in an open circuit. Therefore, the voltage of the reflected wave will be in phase with the voltage of the incident wave.

When a transmission line is terminated in a 25 ohm resistor, some but not all of the incident energy will be absorbed, and some will be reflected back towards the source. The reflected wave will have an amplitude $1/3$ that of the incident wave and the voltage of the two waves will be out of phase by 180 degrees at the load. The phase relationship will change as a function of distance along the transmission line from the load. The valleys of the standing wave pattern will no longer go to zero, and the peaks will be less than that of the open / short circuit.

For more information, see Phase Measurements.
Impedance is another way of expressing reflection data. For more information on Impedance, see Smith Charts.

Summary of the Expressions of Reflection Measurements:
SA Amplifier Harmonics Measurement

- Physical Setup
- Measurement Description
- Step 1. Set Up Amplifier Harmonics Measurement
- Step 2. Validate Receiver
- Step 3. Validate Source

See All Spectrum Analyzer Examples

Physical Setup

Measurement Description

This measurement example helps you understand the basic operation of the Spectrum...
Analyzer application and how to optimize the measurement setup to avoid instrument-generated spurious responses. This example measures the harmonics at maximum gain of an amplifier and confirms that the harmonics are solely caused by the amplifier, not by the PNA source or receivers.

Step 1. Set Up Amplifier Harmonics Measurement

1. On the PNA front panel, press **Preset**.

2. Press **Power > Port Power > Select** and select Port 1.

3. Press **Power > Port Power > Power Level** and set the Port 1 source power to be in a linear region of the amplifier's output response.

4. Press **Freq** and set the start/stop frequency to measure the gain across the amplifier's frequency range.

5. Press **Meas > S-Param > S21**. You should see the amplifier's frequency response as shown in the following example.

6. Press **Search > Main > Max Search** to place a marker on the maximum gain.

7. Press **Marker > Marker -> Functions > Marker -> SA** to view the amplifier's spectrum at the maximum gain. Note that a second channel with Spectrum Analyzer mode is created as shown in the following example.
8. Press Setup > Main > SA Setup... then Resolution Bandwidth and adjust (narrow) the resolution bandwidth to lower the noise floor. The following example shows the lowered noise floor after changing the resolution bandwidth from 1 MHz to 100 kHz.

9. Press Marker > Marker 1-7 > Marker 2 and place the marker on the second harmonic level as shown in the following example.
Step 2. Validate Receiver

The receiver will be validated by monitoring the amplitude of the 2\textsuperscript{nd} harmonic while increasing the receiver B attenuator. The resolution bandwidth will be adjusted if necessary to lower the noise floor. The receiver B attenuator will only affect the power input to the receiver thus affecting the receiver harmonics. However, it does not affect the DUT’s 2\textsuperscript{nd} harmonic. Therefore, if the measured 2\textsuperscript{nd} harmonic does not change when the receiver B attenuator is changed, the receiver B is not contributing the 2\textsuperscript{nd} harmonic measurement.

1. Press Setup > Main > SA Setup....

2. Increase the Receiver B Attenuator then click Apply.

3. Monitor the 2\textsuperscript{nd} harmonic amplitude for any changes.

Step 3. Validate Source

To validate the source, an R1 trace is added and source attenuation is increased to verify if a 2\textsuperscript{nd} harmonic signal is being generated from the Port 1 source.

When source attenuation increases but the set Port 1 output power remains the same, the source outputs more power to maintain the set Port 1 output power. The R1 coupler is before the source attenuator thus it sees higher power from the source than that with the lower source attenuator setting. At a certain point, R1 is compressed and starts generating the 2\textsuperscript{nd} harmonic.

As the R1 receiver has no step attenuators, to verify if it is the source or the R1 receiver generating the
harmonic, measure the same harmonic signal with receiver B but without the DUT (using a Thru connection from Port 1 to Port 2). Attenuators may be added to the receiver B to avoid compression and the resolution bandwidth can be adjusted to lower the noise floor. If receiver B sees the harmonic signal, it is from the source (or both); If the R1 receiver sees the harmonic but receiver B does not, the harmonic is due to the R1 receiver compression.

1. From the menus across the top of the display, press Trace > Trace Setup > Measure..., select R1 to add an R1 trace, then click OK. Refer to the following example.

![New Trace dialog box](image1)

2. Press Freq > Main > SA Setup..., Source tab, then Power and Attenuator... button.

3. Deselect Auto Range for Port 1, increase Source Atten to 20 dB, click OK, then click OK in the Source tab. Refer to the following example.

![Power and Attenuator dialog box](image2)

4. Monitor the 2nd harmonic on the R1 trace for any changes.
5. Press **Freq > Main > SA Setup...**, **Source** tab, then **Power and Attenuator...** button.

6. Increase **Source Atten** to 30 dB, click **OK**, then click **OK** in the **Source Setup** tab. Refer to the following example.

7. Monitor the 2\textsuperscript{nd} harmonic on the R1 trace for any changes.
SA Converter Spurious Measurement

- Physical Setup
- Measurement Description
  - Step 1. Set Up the Converter SC21 Measurement
  - Step 2. Analyze Spurious Signals at IF Output
  - Step 3. Analyze Signals Using Markers

See All Spectrum Analyzer Examples

Physical Setup

Measurement Description

This measurement example sets up a converter Scalar Mixer/Converter (SMC) + Phase measurement, monitors the spurious response on SC21 at specific frequencies, then shows how to use the Spectrum
Analyzer application for analysis.

Step 1. Set Up the Converter SC21 Measurement

1. On the VNA front panel, press **Preset**.

2. Press **Meas > S-Param > Measurement Class**, select **Scalar Mixer/Converter + Phase**, then click **OK**.

3. In the **SMC Setup** dialog that appears, select the **Mixer Setup** tab to configure the SMC setup.

4. Select **Port 3** for LO1. Refer to the following example.

5. Select the **Mixer Power** tab, set **LO1 Power** to 0 dBm, then click **Apply**.

6. Select the **Mixer Frequency** tab, set converter frequencies, then click **Apply**. Refer to the following example.
7. Select the **Power** tab, set Port 1 **Power Level**, check **Power On (All Channels)**, then click **OK**.

8. Place a marker on any unknown signal of the SC21 trace as shown in the following example. (Note that the DUT used in this example has an amplifier stage and a filter.)

---

**Step 2. Analyze Spurious Signals at IF Output**

The following Spectrum Analyzer measurement example will show the IF signal at 1.1 GHz at the output of the converter when the RF is at CW 3.3 GHz. Typical symptoms include an unstable IF
response or intermittent spurious on converter output. To find the cause, the IF, LO, and RF frequency ranges must be analyzed.

1. Press **Marker > Marker -> Functions > Marker -> SA**. The following shows an RF and IF response and is an example of a spurious signal.

![RF and IF response example](image)

2. Press **Freq > Main > SA Setup...** then select the **Source** tab.

3. Change the **Port 1 Type** from CW to Linear (the source will sweep from start to stop frequency).

4. Change the **Port 1 Frequency** range to be the same as the SMC channel, set **Source Number of Steps** to 51, set **SA Sweeps per Source Step** to 1, then click **OK**. Refer to the following example.
5. Ensure that Port 3 is set to CW 2.2 GHz then click OK.

6. Observe the IF response while sweeping the input (RF) signal.

7. Select Freq > Main > SA Setup..., set Start frequency to 500 MHz, and set Stop frequency to 3.5 GHz.

8. Deselect Resolution Bandwidth Auto, change bandwidth to 100 kHz, then click OK. This allows the IF, LO, and RF signals to be viewed on the spectrum as shown in the following example. Note that the signals from the IF port are sweeping as the RF signal sweeps.
Step 3. Analyze Signals Using Markers

1. Press **Trigger** > **Main** > **Hold** to freeze the sweep, then apply markers to signals as shown in the following example.

2. Observe the signals shown in the example above:
   - Marker 4: RF, 3.1 GHz
   - Marker 3: LO, 2.2 GHz
   - Marker 2: IF, 902 MHz
   - Marker 5: spur, 1.3 GHz

   The spur frequency can be derived from the marker information:

   \[ LO - IF = LO - (RF - LO) = 2LO - RF \]

3. Press **Freq** > **Main** > **SA Setup...**, set the stop frequency to 7.5 GHz then click **OK** to observe higher-order components.

4. Press **Trigger** > **Main** > **Continuous** to sweep the channel. The frequency components are sweeping in accordance with the RF sweep.

5. Press **Trigger** > **Main** > **Hold** to investigate the signals. Note that in the following example, the marker 5 frequency is 2LO.
5. Press **Trace** > **Trace Setup** > **Measure**..., select **R3**, select **C**, then click **OK**. This adds an R3 and C receiver measurement to determine if an LO harmonic is from the Port 3 LO source or from the converter circuit. If the signal appears in the R3 reference receiver measurement, then the spur is generated by the Port 3 LO source. If the signal appears in the C test receiver measurement, then the spur is generated by the DUT. Refer to the following examples.

12-Term Error Correction See Error Correction, 12-Term.

1-Port Device A device with a single connector or path to the device's circuitry. Examples include an oscillator and a load.

2-Port Calibration, Full See Error Correction, 12-Term.

2-Port Device A device with two connectors or other paths to the device's circuitry. Examples include filters, SAW devices, attenuators, matching pads, and amplifiers.

3-Term Error Correction See Error Correction, 3-Term.

A

**Active Channel** The highlighted channel affected by front panel functions.

**Active Function Readout** The area of a display screen where the active function and its state are displayed. The active function is the one that was completed by the last key selection or remote programming command.

**Active Hot Parameters (Option S9311xA/B)** Measures the optimum Gamma that provides the maximum delivered power for nonlinear devices.

**Active Marker** The marker on a trace that can be repositioned either by front panel controls or by programming commands.

**Active Trace** A trace that is being swept (updated) with incoming signal information.

**ADC** Analog to Digital Converter

**Address** The identification (represented by a name, label, or number) for a register, location in storage, or any other data source or destination. Examples are the location of a station in a communications network, or a device on the GP-IB.

**ADM** Add-Drop Multiplexer

**Admittance (Y)** The inverse of an impedance (i.e. the ratio of current to voltage). Complex
admittances take the form \( Y = G + jB(t) \).

**ALC** Automatic Level Control. See **Automatic Gain Control**.

**AM** Amplitude Modulation

**AM Group Delay** A technique for the measurement of group delay through a device which utilizes an amplitude modulated (AM) source. Note: The actual delay of the modulation envelope is measured directly with an external scalar detector. Devices that distort the amplitude of a signal cannot be measured. These include amplifiers with automatic gain control (AGC) and devices subject to saturation or power limiting.

**Amplitude Modulation** The process, or result of the process, of varying the amplitude of a carrier signal. The resulting modulated carrier contains information that can be recovered by demodulation. See also **Modulation**.

**Analog** The general class of devices or circuits in which the output varies as a continuous function of the input.

**Annotation** The labeling of specific information on the display (such as frequency or power).

**ANSI** American National Standards Institute: A national membership organization (open to manufacturers, organizations, users, and communications carriers) that approves standards, accredits standards development groups and certificate programs, and represents and coordinates US interests in non-treaty and non-government standards bodies.

**Aperture** The frequency span of the network analyzer used for calculating group delay. The narrower the aperture, the finer the resolution of the group delay variations, but noise is reduced by increasing the aperture.

**Array** A set of numbers or characters that represents any given function.

**ASCII** American Standard Code for Information Interchange

**Attenuation** Denotes a reduction in signal amplitude. The difference between transmitted and received power due to loss through equipment, lines, or other transmission devices; usually expressed in decibels.

**Attenuator** An RF or microwave device used to reduce the power level of a signal by precise, incremental amounts over its entire frequency range.

**Automatic Calibration System** AutoCal: Feature offered on Rohde&Schwarz network analyzers.

**Automatic Gain Control (AGC)** A circuit used in amplifiers and other active devices to keep its RF power level constant as other parameters change, such as frequency. Synonym: Automatic Leveling Control (ALC)
Autoscale An analyzer feature that evaluates waveforms and adjusts controls to stable and enhance the display.

AUX Auxiliary; refers to rear-panel input connector.

Averaging A noise reduction technique that computes each data point based on consecutive sweeps and weighted by a user-specified averaging factor. Each new sweep is averaged into the trace until the total number of sweeps is equal to the averaging factor.

B

B/R The ratio of data sampled at B to the data sampled at R.

Band Pass A range of frequencies that are passed through a device, such as a filter. Frequencies not within the band pass are limited or attenuated. See also Cutoff Frequency.

Bandwidth (BW) The difference between the frequencies of a continuous frequency band within which performance of a device falls within specifications.

Bandwidth Limit The condition prevailing when the system bandwidth is exceeded and signal distortion occurs beyond specifications.

Bandwidth Selectivity A measure of a filter's ability to resolve signals unequal in amplitude. It is the ratio of the 60 dB bandwidth to the 3 dB bandwidth for a given resolution filter (IF). Bandwidth selectivity tells us how steep the filter skirts are. Bandwidth selectivity is sometimes called shape factor.

Binary A method of representing numbers in a scale of two (on or off, high-level or low-level, one or zero). A compact, fast format used to transfer information to and from the analyzer.

BMP Bit-Mapped

Brightness See Color Brightness.

Broadband Device A device that operates over a very wide frequency range and exhibits only small variations in response over that range.

Buffer A storage device used when transmitting information to compensate for a difference in the rate of flow of information between two devices.

Burst Carrier A carrier that is periodically turned off and on. A burst carrier may or may not be modulated.

BUS Basic Utility System
**Bus** One or more conductors used as a path to deliver transmitted information from any of several sources to any of several destinations.

**BW** Bandwidth

**Byte** Eight bits of data representing one character processed as a unit.

---

**C**

**CAD** Computer Aided Design

**CAE** Computer Aided Engineering

**Calibration** In HP instrumentation, the process of periodically (usually annually) verifying an instrument is performing to specifications. A calibration certificate is awarded after verification.

In network analyzers, the process of removing systematic errors from measurements. See Error Correction.

**Calibration Kit** Hardware and software required to perform error correction on a network analyzer for a specific measurement and/or test set.

**Calibration, 2-Port** See Error Correction, 12-Term.

**Calibration, Blackburn** Calibrations of transmission path with corrected source match involving 15 calibration terms. Synonym: 15-term error correction

**Calibration, Frequency Response** The simplest error correction procedure to perform, but only corrects for a few of the twelve possible systematic error terms. Frequency response corrections can be made for reflection measurements, transmission measurements, and isolation measurements.

**Calibration, Interpolation** A user selectable network analyzer feature that calculates (interpolates) new error correction terms from existing terms when there is a change in network analyzer parameters, such as IF bandwidth, power, or sweep time. The resulting error correction is not as accurate as completing a full 2-port calibration.

**Calibration, Port Extension** See Port Extension.

**Calibration, Reference Plane** See Reference Plane.

**Calibration, Set Z** Sets the system impedance, usually 50 or 75 ohms.

**Calibration, SOLT** A calibration using four known standards: Short-Open-Load-Through. Also known as a full two-port calibration and 12-term error correction. See also Error Correction.
Calibration, TRL and LRM A calibration used in environments where the DUT cannot be connected directly to the network analyzer ports, (MMIC, microstrip, beam-lead diodes etc.). Thru-Reflect-Line (TRL) and M (Match) standards are fabricated and used because known high-quality standards are not readily available. The requirements for characterizing these standards are less stringent, but the calibration is not as accurate as the traditional full two-port calibration using S-O-L-T standards. The terms are used interchangeably (TRL, LRL, LRM etc.) but they all refer to the same basic calibration method.

Characteristic Impedance The impedance looking into the end of an infinitely long lossless transmission line.

Color Brightness A measure of the intensity (brightness) of a color.

Command A set of instructions that are translated into instrument actions. The actions are usually made up of individual steps that together can execute an operation.

Continuous Sweep Mode The analyzer condition where traces are automatically updated each time trigger conditions are met.

Controller A device capable of specifying the talker and listeners for an information transfer. An external computer connected to an instrument to control its operation.

Corrected Measurements made after performing error correction.

Coupler See Directional Coupler.

CPU Central Processing Unit

Crosstalk The occurrence of a signal at one port of a device being affected by a signal in any other path. Isolation is the measurement of crosstalk.

Cursor An electronically generated pointer that moves across the display to manipulate controls.

Cutoff Frequency In filters, the frequency at which attenuation is 3dB below the band pass signal level, known as the 3dB points.

CW Continuous wave: A single frequency (rather than a swept frequency).

D

DAC Digital to Analog Converter

dB Decibel: a relative unit of measure. The ratio in dB is given by: $10 \log_{10} (P_1/P_2)$ where $P_1$ and $P_2$ are the measured powers. The dB is preferred instead of arithmetic ratios or percentages because when components are connected in series, their effect on power, expressed in dB, may be arithmetically
added and subtracted. For example, if a 3dB attenuator is connected to a 10dB amplifier, the net gain of the two components is (-3dB + 10dB = +7dB).

dBm Absolute unit of measure in decibels: 0dBm = 1 mW. The conventions of the dB (adding and subtracting) continue to apply.

DBMS Database Management System

DC Direct Current

Default A known set of conditions used in the absence of user-defined conditions.

Delay See Group Delay.

Demodulation The process of recovering from a modulated carrier, information in the form of a signal having essentially the same characteristics as the original modulating signal. Recovery of the modulating signal accomplished by signal detection.

Detection The process of demodulating signal carriers. There are two basic ways of providing signal detection in network analyzers: Diode detectors (used in broadband applications) and heterodyning, (used in narrowband applications).

Detector, Diode A device used to convert a RF signal to a proportional DC level. If the signal is amplitude modulated, the diode strips the RF carrier signal from the modulation. Many sources used with scalar analyzers are amplitude modulated with a 27.778 kHz signal and then detected in the network analyzer. Phase information on the signal carrier is lost in diode detection.

Deviation from Linear Phase Linear phase refers to the nature of the phase shift of a signal through a device. The phase is linear if a plot of phase shift versus frequency is a straight line using linear scales. Deviation from linear phase causes signal distortion.

Digital Pertaining to the class of devices or circuits in which the output varies in discrete steps.

Digital Demodulation Describes a technique of extracting the information used to modulate a signal. Digital signal processing algorithms are used on the signal after it has been converted from an analog to a digital form (digitized).

Dimension To specify the size of an array. The number of array rows or columns.

Directivity In a 3-port directional coupler, the ratio of the power present at the auxiliary port when the signal is traveling in the forward direction to the power present at the auxiliary port when the same signal is traveling in the reverse direction.

Directional Coupler A 3-port device typically used for separately sampling the backward (reflected) wave in a transmission line.
**Disk** A circular, magnetic storage medium.

**Display** Noun: See Screen.

Verb: To show annotation and measurement data on the display.

**Display Detector Mode** The manner in which analog, video information is processed prior to being digitized and stored in memory.

**Display Dynamic Accuracy** The amplitude uncertainty, usually in dB, over the display dynamic range.

**Display Dynamic Range** The amplitude range, in dB, over which the display dynamic accuracy applies.

**Display Formats** Graphical formats for displaying measurement data. These include single channel, overlay (multiple traces on one graticule), split (each trace on separate graticules).

**Display Modes** The ways in which measurement data can be presented graphically. On a network analyzer, the choices are Cartesian/rectilinear (XY plot with log or linear magnitude, phase, group delay, SWR, real and imaginary, and dBV, dBmV and dBuV), polar (magnitude and angle), magnitude and phase, and Smith chart. Not all display modes are available on all network analyzers. In addition, displays can present this information in various combinations of traces. Common modes are dual, (the ability to display more than one trace, usually over the same frequency range), and alternate, (the ability to display more than one trace, each with different frequency range and type).

**Display Phase Dynamic Accuracy** The phase measurement uncertainty, usually in degrees, for measurements whose units are in degrees.

**Display Points** The total number of measurement points made in a single measurement. The points can be in units of frequency, power, or time. The number of points often dictates measurement speed, resolution, and aperture.

**Display Trace Noise, Magnitude** The amplitude uncertainty of the trace, in dB, due to random noise in the test system.

**Display Trace Noise, Phase** The phase uncertainty of the trace, in degrees, due to random noise in the test system.

**Display Type** The type of display screen built into the analyzer. Data can be displayed as a raster drawing (a computer-like dot map) or as a vector drawing (lines drawn on the display). Color and display standard can also be specified as monochrome (single color), or color (two or more colors). The format standard may also be specified, such as VGA or SVGA, for IBM-compatible personal computers.

**Distortion** Deterioration of a signal's quality due to the nonlinear characteristics of a device or system.
transfer function. Distortion is measured as a combination of the changes in amplitude, frequency and phase of signal at the output of a device or system as compared to the signal at the input.

**Drift** The slow change in signal frequency.

**DSP** Digital Signal Processing

**DUT** Device Under Test

**DVM** Digital Volt Meter

**Dynamic Range** In a receiver, the range of signal levels, from minimum to maximum, that can be reliably measured simultaneously. Dynamic range allows small signals to be measured in the presence of large signals. Source power and receiver compression usually limits the maximum boundary to dynamic range. Receiver residual responses and noise floor usually limit the minimum power boundary.

---

**E**

**ECal** See **Electronic Calibration**.

**Electrical Delay** A simulated variable length of lossless transmission line, added to or subtracted from a receiver input, to compensate for interconnecting cables. The firmware equivalent of mechanical or analog "line stretchers" in other network analyzers.

**Electronic Calibration (ECal)** A calibration system for electronic calibration of RF and microwave vector network analyzers. The electronic calibration system creates a twelve-term, two-port error model and then provides a confidence check of the calibration. The Ecal system consists of a repeatable, variable-impedance, solid-state calibration standard and a mainframe control unit which interfaces with the 8510, 8720 series, and the 8753 network analyzers or a USB module which interfaces with the PNA series network analyzers.

**EMC** Electro-Magnetic Compatibility

**EMI** Electro-Magnetic Interference: Unintentional interfering signals generated within or external to electronic equipment. Typical sources could be power-line transients, noise from switching-type power supplies and/or spurious radiation from oscillators. EMI is suppressed with power-line filtering, shielding, etc.

**Engage** To activate a function.

**Enter** The process of inputting information.

**EPROM** Electronically Programmable, Read-Only Memory
**Error Correction** In network analyzers, a process that removes or reduces systematic (repeatable) measurement errors by measuring known standards from a calibration kit. Synonym: measurement calibration

**Error Correction, 3-Term** Used to remove systematic measurement errors on a device with one port, such as a load.

**Error Correction, 12-Term** Correction for a two port device using six parameters:
- Directivity
- Source match
- Load match
- Reflection frequency response
- Transmission frequency response
- Isolation

To completely characterize a two-port device, these six parameters must be characterized in the forward and reverse directions, making a total of 12 terms. The user usually has the option of omitting isolation from the correction process. Synonym: Full two-port error correction

**Error Correction, 1-Port** Corrects a test set for port 1 or port 2 directivity, frequency response, and source match errors. The process requires three known standard terminations, for example, open, short, and load.

**Error Message** A message on a display that indicates an error condition. Missing or failed hardware, improper user operation, or other conditions that require additional attention can cause an error condition. Generally, the requested action or operation cannot be completed until the condition is resolved.

**ESD** Electro Static Discharge

**Ethernet** A network that adheres to the IEEE 802.3 Local Area Network standard.

**Ethernet address** A hexadecimal number which is used to identify a machine on a network. Each analyzer is assigned a unique Ethernet address at the factory and it is stored in the analyzer's ROM.

**External trigger signal** A TTL signal that is input to an analyzer and initiates a measurement sweep or similar event, making the measurements synchronous with the external triggering source.

**F**

**Filter** A passive device that allows some frequencies to pass and attenuates others, depending on the type and specifications. A high-pass filter passes frequencies above the cutoff frequency, a low-pass filter passes frequencies below the cutoff frequency, and a band-pass filter passes frequencies between
two specific frequencies.

**Firmware** An assembly made up of hardware and instruction code. The hardware and instruction code is integrated and forms a functional set that cannot be altered during normal operation. The instruction code, permanently installed in the circuitry of the instrument, is classified as ROM (read only memory). The firmware determines the operating characteristics of the instrument or equipment.

**Flatness** The amplitude and phase response of a device under test (DUT), a signal source, a receiver, or a combination of these. See also Frequency Response.

**FM** Frequency Modulation

**Frequency** The number of periodic oscillations, vibrations, or waves per unit of time, usually expressed in cycles per second, or Hertz (Hz).

**Frequency Accuracy** The uncertainty with which the frequency of a signal or spectral component is indicated, either in an absolute sense or relative to another signal or spectral component. Absolute and relative frequency accuracies are specified independently.

**Frequency Range** The range of frequencies over which a device or instrument performance is specified.

**Frequency Resolution** The ability of a network analyzer to measure device characteristics at closely spaced frequencies and display them separately. Resolution of equal amplitude responses is determined by IF bandwidth. Resolution of unequal amplitude responses is determined by IF bandwidth and bandwidth selectivity.

**Frequency Response** The peak-to-peak variation in the displayed amplitude response over a specified center frequency range. Frequency response is typically specified in terms of dB, relative to the value midway between the extremes.

**Frequency Span** The magnitude of the displayed frequency component. Span is represented by the horizontal axis of the display. Generally, frequency span is given as the total span across the full display. Some analyzers represent frequency span (scan width) as a per-division value.

**Frequency Stability** The ability of a frequency component to remain unchanged in frequency or amplitude over short and long-term periods of time. Stability refers to an oscillator's ability to remain fixed at a particular frequency over time.

**Front Panel Key** Keys that are located on the front panel of an instrument. The key labels identify the function the key activities. Numeric keys and step keys are two examples of front panel keys.

**Full 2-Port Calibration** See Error Correction, 12-Term.

**Function** The action or purpose that a specific item is intended to perform or serve. The network
analyzer contains functions that can be executed via front panel key selections, or through programming commands. The characteristics of these functions are determined by the firmware in the instrument. In some cases, a DLP (downloadable program) execution of a function allows you to execute the function from front panel key selections.

**Fundamental Frequency** In any waveform, the lowest frequency component; all other components are harmonics. A pure sinusoid has only one component, the fundamental.

---

**G**

Gb Gigabit

GB Gigabyte

GHz Gigahertz

GIF Graphics Interchange Format - Standard graphic format to store bitmapped graphics files.

Giga Prefix for one billion.

GP I/O General Purpose Input / Output; a connector usually on the back of an instrument that allows communication with other test equipment, external test sets, switches, and computers that enable the instrument to be triggered or to trigger external equipment. An example is a foot switch that continues or cycles a measurement, allowing the operator to use both hands on the test hardware.

GPIB General Purpose Interface Bus - IEEE 488 bus is interconnect bus and protocol, allows linking of instruments and computer.

Graticule (or Grid) Enclosed area where waveform is displayed on instrument. Tick marks, on frame or axis, are a scaling aid for making visual measurements.

Group Delay A measure of the transit time of a signal through a DUT versus frequency. Group delay can be calculated by differentiating the DUT's insertion-phase response with respect to frequency. See also **AM Group Delay** and **Deviation from Linear Phase**.

GUI Graphical User Interface

---

**H**

Hardcopy Paper copy of data.

Hardkey A front-panel key, which engages a single analyzer function or presents a single menu of softkeys.
Horizontal Reference  See Reference Level.

Horizontal Resolution The analyzer's ability to take closely spaced horizontal data points over the full sweep.

Host Computer  A computer or device on a network that provides end users with services such as computation and database access and that usually performs network control functions.

Host Name  A unique name that is used to identify each host machine on a network. The host name is directly linked to, and can usually be used in place of, the IP address. The user or the system administrator usually creates the host name.

HP  Hewlett-Packard Company

HPGL  Hewlett-Packard Graphics Language

HP-IB  Hewlett-Packard Interface Bus. A parallel interface that allows "daisy chaining" of more than one device to a port on a computer or instrument. Interface protocol is defined in IEEE 488.2; equivalent to the industry standard GPIB.

HTTP  HyperText Transfer Protocol: Used to carry World Wide Web (WWW) traffic.

Hue  The dimension of color referred to a scale of perceptions ranging from red through yellow, green, and blue, and back to red. A particular gradation of color, tint, shade.

I

I/O Input/Output

I/O Path  Input/Output Path

IEEE  Institute of Electrical and Electronic Engineers

IF  Intermediate Frequency: the frequency at which a signal is processed after mixing.

Impedance  The ratio of voltage to current at a port of a circuit, expressed in ohms.

Initialize  The process that assigns information locations to a disk to prepare the magnetic media to accept files.

Input  A path intended for putting a signal into an instrument.

Most network analyzers have either 3 (labeled A, B, and R) or 4 inputs (labeled A, B, R1, and R2). Inputs are not the same as channels.

Input Attenuator  An attenuator between the input connector and the first mixer of a spectrum
analyzer (also called an RF attenuator). The input attenuator is used to adjust the signal level incident to
the first mixer, and to prevent gain compression due to high-level or broadband signals. It is also used
to set the dynamic range by controlling the degree of internally-generated distortion. For some
analyzers, changing the input attenuator settings changes the vertical position of the signal on the
display, which then changes the reference level accordingly. In Keysight microprocessor-controlled
analyzers, the IF gain is changed to compensate for changes in input attenuator settings. Because of
this, the signals remain stationary on the display, and the reference level is not changed.

**Insertion Loss** The difference between the power measured before and after the insertion of a device.
The attenuation between the input and output of a device.

**Intensity** Brightness; emitting or reflecting light; luminosity.

**Interface** A connection that allows a common communication link between two or more instruments.

**Intermodulation Distortion** Undesired frequency components resulting from the interaction of two or
more spectral components passing through a device having nonlinear behavior, such as a mixer or an
amplifier. The undesired components are related to the fundamental components by sums and
differences of the fundamentals and various harmonics. The algorithm is: \( f_1 \pm f_2, 2xf_1 \pm f_2, 2xf_2\pm f_1, \)
\(3xf_1 \pm 2x f_2, \) and so on.

**Internet** The connection of two or more distinct networks. Often a gateway or router is used to make
the connection.

**Interpolate** To determine a value of a signal between two adjacent points by a procedure or algorithm.

**IP** Internet Protocol

**IP Address** Internet protocol address: a unique number that is assigned to each device which is to be
connected to a TCP/IP network. Before using an analyzer on a network, your network administrator
will need to assign an IP address. An IP address consists of a 32-bit value presented in decimal dot
notation: 4 octets (bytes) separated by a dot.

**ISDN** Integrated Services Digital Network: A standard digital service capability that features one or
more circuit-switched communication channels capable of carrying digital voice, data, or image
signals, a packet-switched channel for out-of-band signaling and control. In addition, ISDN provides a
collection of standard and optional features that support information productivity for the user,
providing higher-speed Internet access than analog systems.

**ISO** International Standards Organization

**Isolation** A specification or measure of the immunity that one signal has to being affected by another
adjacent signal. The occurrence is known as crosstalk.

**Isolator** An RF device used for providing isolation between paths and components. Made from a 3-port
circulator, the third port being terminated in a 50ohm load.

---

J

---

K

Kilo Prefix for one thousand.

KB Kilobyte

Kb/s Kilobytes per second

---

L

LAN Local Area Network

LANS Local Area Network System

LCD Liquid Crystal Display

LED Light Emitting Diode

LFE Low Frequency Extension

LIF Logical Interchange Format (used for older HP disk drives/computers)

Limit Lines Lines input by the user that overlay the analyzer's measurement data to allow automatic detection of data that is out of the acceptable range. Pass/Fail annotation, audio alarms, or electronic output can be triggered to notify the operator or on-line computer program of the over-limit condition.

Limit-Line File The user-memory file that contains the limit-line table entries.

Limit-Line Table The line segments of a limit line are stored in the limit-line table. The table can be recalled to edit the line segments, then restored in the limit-line file.

Linear Device A device in which the output is continuously proportional to the input.

LO Local Oscillator. In a superheterodyne system, the LO is mixed with the received signal to produce a sum or difference equal to the intermediate frequency (IF) of the receiver.

LO Feedthrough The response that in a superheterodyne system when the first local oscillator frequency is equal to the first IF.

Load A one port microwave device used to terminate a path in its characteristic impedance.
**Load Match** A measure of how close the device's terminating load impedance is to the ideal transmission line impedance. Match is usually measured as return loss or standing wave ratio (SWR) of the load.

**Local Lock Out** A condition or command that prevents analyzer front-panel entries (and disables the Local key).

**Local Operation** To operate manually from the front panel.

**Log** Logarithm

**Log Display** The display mode in which vertical deflection is a logarithmic function of the input signal amplitude. Log display is also called logarithmic display. The display calibration is set by selecting the value of the reference level position and scale factor in dB per division.

**LRM** Line-Reflect-Match. See Calibration, TRL, and LRM.

---

**M**

**Magnitude** The amplitude of a signal measured in its characteristic impedance without regard to phase. See also Scalar.

**Marker** A graphical symbol along a display trace that is annotated with measurement characteristics of that specific data point.

**Marker Functions** Mathematical or statistical computation on the data of one or more markers to provide the operator more information. For example, the marker delta function calculates and displays the difference between two markers.

**Maximum Input Level** The maximum signal power that may be safely applied to the input of an analyzer. The maximum input level is typically 1 W (+30 dBm) for Keysight spectrum analyzers.

**MB** Megabyte

**Measurement Uncertainty** The quantified amount of error in a measurement situation. Calibrations are intended to reduce the amount of uncertainty. The following are sources of measurement errors that lead to uncertainty:

- Systematic errors (imperfections in calibration standards, connectors, cables, and instrumentation)
- Random errors (noise, connector repeatability)
- Drift (source and instrumentation)
**Mega** Prefix for one million.

**Memory** A storage medium, device, or recording medium into which data can be stored and held until some later time, and from which the entire original data may be retrieved.

**Memory Card** A small memory device shaped like a credit card that can store data or programs.

**Menu** The analyzer functions that appear on the display and are selected by pressing front panel keys. These selections may invoke a series of other related functions that establish groups called menus.

**MHz** Megahertz

**milli** Prefix for one-thousandth.

**Modem** Modulator/Demodulator

**Modulation** The process, or the result of the process, of varying a characteristic of a carrier signal with an information-bearing signal, causing the carrier to contain the information. See AM and FM.

**Modulation Distortion (Option S93070xB)** Measures the nonlinear behavior of an RF microwave amplifier under a modulated signal.

**Monitor** Any external display.

**Monochrome** Having only one color (chromaticity).

**ms** Millisecond

**mW** Milliwatt: one thousandth of a watt

**Multisync** A type of monitor that can synchronize its horizontal sweep to various frequencies within a specified range.

---

**N**

**Narrowband** In network analysis, the frequency resolution of the analyzer's receiver that is sufficiently narrow to resolve the magnitude and phase characteristics of narrowband devices. The reduced receiver bandwidth usually decreases the noise floor of the receiver, providing more measurement amplitude range.

**Narrowband Device** A device whose transfer characteristics are intended to operate over a very narrow frequency range and are designed to provide well-defined amplitude responses in that range, such as a band pass filter.

**Network Analysis** The characterization of a device, circuit, or system derived by comparing a signal
input going into the device to a signal or signals coming out from the device.

**NIST National Institute of Standards and Technology**

**Nit** The unit of luminance (photometric brightness) equal to one candela per square meter.

**Noise** Random variations of unwanted or disturbing energy in a communications system from man-made and natural sources that affects or distorts the information carried by the signal. See also Signal-to-Noise Ratio.

**Noise Figure (F):** For a two-port device, a measure of how the noise generated inside the device degrades the signal-to-noise ratio of a signal passing through the device at 290 degrees, usually expressed in dB.

**Noise Floor** The analyzer's internal displayed noise. The noise level often limits how small a signal magnitude can be measured. In network analysis, noise floor is measured with the test ports terminated in loads, full two-port error correction, 10 Hz IF bandwidth, maximum test port power, and no averaging during the test.

**Non-Insertable Devices** In measurement calibration, a device that cannot be substituted for a Zero-Length Through Path. It has the same type and sex connectors on each port, or a different type of connector on each port.

**Nonvolatile Memory** Memory data that is retained in the absence of an ac power source. This memory is typically retained with a battery. Refer also to battery-backed RAM.

**Normalize** To subtract one trace from another to eliminate calibration data errors or to obtain relative information.

---

**O**

**Offset** To move or set off a determined amount. Used in instruments for offsetting frequencies, limits, delay, loss, impedance, etc.

**Output Attenuation** The ability to attenuate the signal, the source, in order to control its power level.

---

**P**

**PC Personal Computer**

**PDF Portable Document Format (used on the Web)**

**Parser, Command** Reads program messages from the input queue of a device in the order they were
received from the controller. The parser determines what actions the analyzer should take. One of the most important functions of the command parser is to determine the position of a program message in the analyzer SCPI command tree. When the command parser is reset, the next element it receives is expected to arise from the base of the analyzer command tree.

**Peak Search** A function on an analyzer that searches for the largest response and places a marker on it.

**Phase** The fractional part of a cycle through which an oscillation has advanced, measured from an arbitrary starting point; usually measured in radians or degrees. In network analysis, the phase response of the device under test is the change in phase as a function of frequency between the input stimulus and the measured response.

**Port** The physical input or output connection of an instrument or device.

**Port Extension** Redefining the reference plane to other than that established at calibration. A new reference plane is defined in seconds of delay from the test set port.

**Positive Peak** The maximum, instantaneous value of an incoming signal.

**Postscript (.ps files)** Stores bitmapped graphics files in an encapsulated format for direct use by postscript printers.

**Power, Max Input** The upper limit to input power for which the specifications apply. Some specifications may have different levels of maximum inputs. For example, compression power maximum is usually higher than the harmonic distortion maximum.

**Power, Safe Input** The input power, usually in dBm, allowed without damaging the instrument.

**Preset** A pre-defined instrument state (that also runs an analyzer self-test). The action of pushing the Preset key.

**Protocol** A set of conventions that specify how information will be formatted and transmitted on a network, and how machines on a network will communicate.

---

**Q**

**Q or Q Factor** The ratio of energy stored to energy lost in a resonant circuit. High Q indicates a sharp resonance response over frequency.

**Query** Any analyzer programming command having the distinct function of returning a response. These commands may end with a question mark (?). Queried commands return information to the computer.
Expression for complex impedance, where $r$ represents the resistive portion and $x$ represents the reactive portion.

**R Channel** Reference Channel

**RAM** Random Access Memory, or read-write memory: A storage area allowing access to any of its storage locations. Data can be written to or retrieved from RAM, but data storage is only temporary. When the power is removed, the information disappears. User-generated information appearing on a display is RAM data.

**ROM** Read Only Memory: A storage area that can be read only; it cannot be written to or altered by the user. In instruments, the storage area that contains the "brains" or operational programming; the firmware.

**Receiver** A circuit or system designed for the reception and/or measurement of signals in a specified frequency spectrum.

**Receiver Dynamic Range** See Dynamic Range.

**Reference Level** An instrument function that allows the user to set the amplitude value at the reference position. On network analyzers, the reference position is also selectable. On some spectrum analyzers, the reference position is fixed at the top of the display.

**Reference Plane** The electrical location at which a network analyzer assumes the system connectors and fixturing ends and the DUT begins. The reference plane is set by using calibration standards with known electrical length. The closer the reference plane is to the device under test (DUT), the better the characterization of the device because of the elimination of test system uncertainties.

**Reference Receiver** In a network analyzer, the receiver that measures signals as they come out of the source, before they are incident on the test port and DUT. Typically, these signals are used to compare with the signal at the Test Port Receiver, to determine the affect that the DUT has on the signal. In a 2-port network analyzer, these are typically named 'R1' (port 1) and 'R2' (port 2). See a block diagram of the receivers in your PNA.

**Reflection** The phenomenon in which a traveling wave strikes a discontinuity and returns to the original medium.

**Reflection Coefficient** The ratio of the reflected voltage to the incident voltage into a transmission line or circuit. If a transmission line is terminated in its characteristic impedance, the reflection coefficient is zero. If the line is shorted or open the coefficient is 1. See also Return Loss and SWR.

**Reflection Measurements** Measurements that characterize the input and/or output behavior of the device under test (DUT). Measured as the ratio of the reflected signal to the incident signal as a
function of frequency. Parameters are called return loss, reflection coefficient, impedance, and standing wave ratio (SWR), all as a function of frequency. See also S-Parameters.

Remote A mode of operation where another device (or computer) controls an instrument via the HP-IB. In this mode, the instrument front panel keys are disabled. Front panel operation is called local operation.

Remote Programming The automatic operation of an instrument by a computer, usually through a HP-IB, LAN, or RS-232 link.

Resolution The ability of a receiver to resolve two signals.

Resolution Bandwidth The ability of a spectrum analyzer to display adjacent responses discretely (Hertz, Hertz decibel down). This term is used to identify the width of the resolution bandwidth filter of a spectrum analyzer at some level below the minimum insertion loss point (maximum deflection' point on the display). Typically, it is the 3 dB resolution bandwidth that is specified, but in some cases the 6 dB resolution bandwidth is specified.

Return Loss The amount of dB that the reflected signal is below the incident signal. If zero signal is reflected, the impedance of the device is equal to the characteristic impedance of the transmission system, and return loss is infinite. If the entire incident signal is reflected, the return loss is zero. See also S-Parameters, Reflection Coefficient, and SWR.

Reverse Measurement The measurement of a device from output to input.

RF Radio Frequency (from approximately 50 kHz to approximately 3 GHz). Usually referred to whenever a signal is radiated through the air.

ROM Read Only Memory

S

S/N Signal-to-Noise Ratio

Sampler An electronic component that captures the signal level and phase across a known impedance at a uniform rate. In Network Analyzers, this sampling rate must be sufficiently high and precisely timed to make accurate measurements. Network analyzers typically have three or four samplers or mixers.

Sampler Bounce The leakage or crosstalk between a network analyzer's samplers. Delay in this crosstalk caused by leakage transmission propagation, give the interference its "bounce" appearance. Sampler bounce causes an increase in the noise level of the affected channel, reducing the sensitivity of the analyzer.
**Saturation** The degree of color purity, on a scale from white to pure color.

**Scalar** A quantity that has magnitude but no phase. A network analyzer capable of measuring only magnitude.

**Scale Factor** The display vertical axis calibration in terms of units per division.

**SCPI** Standard Commands for Programmable Instruments

**Screen** The physical surface of the CRT or flat panel upon which the measurement results, setup information, softkey definitions, and other instrument communication is presented.

**Self-Test** A group of tests performed at power-up (or at preset) that verify proper instrument operation.

**Sensitivity** The minimum input signal required to produce a specified output signal having a specified signal-to-noise ratio, or other specified criteria.

On a spectrum analyzer, the level of the smallest sinusoid that can be observed, usually under optimized conditions of minimum resolution bandwidth, 0 dB input attenuation, and minimum video bandwidth.

The normalized change in YIG component's center frequency resulting from a change in tuning coil current, specified in MHz/mA.

**Serial Prefix** The five-character prefix that begins an instrument serial number; used to represent versions of firmware or hardware changes that have occurred.

**Server** A device that is configured to provide a service to other devices on a network, such as shared access to a file system or printer.

**Signal-to-Noise Ratio** SNR: The ratio of the amplitude of the desired signal to the amplitude of noise signals, usually expressed in dB and in terms of peak values for impulse noise and root-mean-square values for random noise.

**Single Sweep Mode** The spectrum analyzer sweeps once when trigger conditions are met. Each sweep is initiated by pressing an appropriate front panel key, or by sending a programming command.

**Small Signal Gain Compression** A situation when the input signal's measured amplitude is less than its actual level due to overloading of the network analyzer's input mixer; the analyzer is operating nonlinearly. For broadband analyzer detectors, a signal other than the one under test can put the analyzer into this gain compressed mode, thereby making even lower level signals appear at a lower level than actual. The broadband mode measures all the power incident to the analyzer, not just the signals at the frequency of interest.

**Smith Chart** A graphical mapping of the complex reflection coefficient into normalized complex impedance. Circles on the chart represent constant resistance and radiating lines orthogonal to the
circles represent constant reactance. The center of the chart represents the characteristic impedance of the transmission system. Any point on the chart defines a single complex impedance. A line on the chart represents changing impedance over frequency.

SOLT Short-Open-Load-Through calibration. See also Calibration, SOLT.

Source A device that supplies signal power; a sweep oscillator or synthesized sweeper.

Source Amplitude Accuracy The amplitude uncertainty, in dB, of the source power readout.

Source Amplitude Flatness The amplitude flatness, in dB, of the source power over the frequency range specified.

Source Frequency Resolution The smallest unit of frequency which can be set and/or measured, in Hz.

Source Frequency Time Base Accuracy A measure of the analyzer's frequency stability measured in parts per million (ppm. or 1 part in 10E6). For example, a stability of ±5.0 ppm means that an analyzer will measure 1 MHz to an accuracy of ±5 x 10-6 x 10E6 Hz = ±5 Hz.

Source Frequency Time Base Stability A measure of the analyzer's time base accuracy over time and temperature. Typically the time base accuracy will be specified for 1 year. A typical temperature frequency stability is ±10 ppm for 25° C ± 50 C.

Source Harmonics The level of harmonics generated by the analyzer's signal source, in dBc from the fundamental.

Source Match A measure of how close the signal source impedance is to the ideal transmission line impedance of the test system. Match is usually measured as return loss or standing wave ratio (SWR) of the source.

Span The stop frequency minus the start frequency. The span setting determines the horizontal-axis scale of the analyzer display.

Span Accuracy The uncertainty of the indicated frequency separation of any two signals on the display.

S-Parameters (Scattering Parameters) A convention used to characterize the way a device modifies signal flow using a network analyzer. A two port device has four S-parameters: forward transmission (S21), reverse transmission (S12), forward reflection (S11), and reverse reflection (S22).

Spectrum Analyzer (Option Sx090A/B) Spectrum Analyzer function for component measurements.

Stop/Start Frequency Terms used in association with the stop and start points of the frequency measurement range. Together they determine the span of the measurement range.
Storage States The number of settings, programs, traces, and other parameters available to be saved, cataloged, and recalled at any one time.

Storage, Disk An internal or external digital storage disk for saving test data, instrument settings, IBASIC programs, and other measurement parameters. Storage formats include MS-DOS (R) and HPs standard LIF with binary, PCX, HP-GL, or ASCII data formats.

Structural Return Loss Poor return loss in cable due to a periodic fault such as a periodic dent caused by dropping the cable spool or by the cable pulling process during manufacture.

Supplemental Characteristics Typical but non-warranted performance parameters, denoted as "typical", "nominal" or "approximate".

Sweep The ability of the source to provide a specified signal level over a specified frequency range in a specified time period. Also see Sweep Mode and Sweep Type.

In data processing mode, a series of consecutive data point measurements, taken over a sequence of stimulus values.

Sweep Mode The way in which a sweep is initiated or selected, e.g., single, continuous, alternate, or chopped.

Sweep Type The method of sweeping the source, e.g., linear, log, or frequency step.

Sweeper A signal source that outputs a signal that varies continuously in frequency.

SWR Standing Wave Ratio, calculated as \((1 + \pi) / (1 - \pi)\) where \(\pi\) is the reflection coefficient.

Sync Synchronization, or Synchronized

Syntax The grammar rules that specify how commands must be structured for an operating system, programming language, or applications.

System Dynamic Range The difference between the maximum receiver input level and the receiver's noise floor. System dynamic range applies to transmission measurements only, since reflection measurements are limited by directivity.

TDR/TDT (Option S93011A/B) Time Domain Reflectometry/Time Domain Transmission.

T/R See Transmission/Reflection.

Termination A load connected to a transmission line or other device.
**Test Limit** The acceptable result levels for any given measurement.

**Test Port** See Port.

**Test Port Receiver** In a network analyzer, the receiver directly behind the test ports, used to measure the signal as it is reflected off, or transmitted through, the DUT. This signal is typically compared with the signal at the Reference Receiver to determine how the DUT affects a signal. In a 2-port network analyzer, these are typically named 'A' (port 1) and 'B' (port 2). See a block diagram of the receivers in your PNA.

**Test Set** The arrangement of hardware (switches, couplers, connectors and cables) that connect a test device input and output to the network analyzer's source and receiver to make s-parameter measurements.

**Third Order Intercept** TOI: The power input to a non-linear device that would cause third order distortion at the same power level. TOI is a measurement to determine the distortion characteristics of a mixer or receiver. The higher the value, the more immune the receiver to internal distortion.

**Thru** Through line: A calibration standard. See Calibration, SOLT.

**Tint** A shade of color; hue.

**Toggle** To switch states, usually to change a function from on to off, or off to on.

**TOM** Thru-Open-Match: A Rohde&Schwarz term to describe a calibration method.

**Trace** A series of data points containing frequency and response information. The series of data points is often called an array. The number of traces is specific to the instrument.

**Tracking** The ability of the analyzer's receiver to tune to the source frequency over the measurement frequency range. Poor tracking results in amplitude and phase errors due to the receiver IF circuits attenuating and delaying the device under test output.

**Transfer Function** The ratio of the output signal to the stimulus signal, both as a function of frequency.

**Transmission** See Transmission Measurements.

**Transmission Intermodulation Spurious** A measure of the capability of the transmitter to inhibit the generation of intermodulation distortion products. Intermodulation spurious is sometimes called intermodulation attenuation.

**Transmission Measurements** The characterization of the transfer function of a device, that is, the ratio of the output signal to the incident signal. Most common measurements include gain, insertion loss, transmission coefficient, insertion phase, and group delay, all measured over frequency. See also S-Parameters.
**Transmission/Reflection (T/R)** Refers to the suite of measurements made by a scalar or vector network analyzer to characterize a device's behavior over frequency. See also S-Parameters.

**Transparent** Something that is not visible to the user. Usually a procedure that occurs without the user's initiation or knowledge.

**Trigger** A signal that causes the instrument to make a measurement. The user can select several options for triggering, such as manual, continuous, or external (for synchronizing measurements to an external source).

**TRL** Through-Reflect-Line. See Calibration, TRL and LRM.

**TTL** Transistor-Transistor Logic

**Two-Port Error Correction** See Error Correction, 12-Term.

**U**

**Uncorrected** Measurements made without performing error correction.

**Uncoupled Channels** Stimulus or receiver settings allowed to be set independently for each channel.

**UNI** User-Network Interface: The point at which users connect to the network.

**Units** Dimensions on the measured quantities. Units usually refer to amplitude quantities because they can be changed. In analyzers with microprocessors, available units are dBm (dB relative to 1 mW dissipated in the nominal input impedance), dBmV (dB relative to 1 mV), dBW (dB relative to 1 1W), V (volts), W (watts).

**V**

**Variable** A symbol, the value of which changes either from one iteration of a program to the next, or within each iteration of a program.

**Vector** A quantity that has both magnitude and phase.

A network analyzer capable of measuring both magnitude and phase.

**VEE** Visual Engineering Environment (Keysight software product)

**Velocity Factor** A numerical value related the speed of energy through transmission lines with different dielectrics (.66 for polyethylene). Used in making time domain measurements.

**Vertical Resolution** The degree to which an instrument can differentiate amplitude between two
signals.

**Video** An electrical signal containing timing, intensity, and often color information that, when displayed, gives a visual image.

**Video Bandwidth** In spectrum analyzers, the cutoff frequency (3 dB point) of an adjustable low-pass filter in the video circuit. When the video bandwidth is equal to or less than the resolution bandwidth, the video circuit cannot fully respond to the more rapid fluctuations of the output of the envelope detector. The result is a smoothing of the trace, or a reduction in the peak-to-peak excursion, of broadband signals such as noise and pulsed RF when viewed in broadband mode. The degree of averaging or smoothing is a function of the ratio of the video bandwidth to the resolution bandwidth.

**Video Filter** In spectrum analyzers, a post-detection, low-pass filter that determines the bandwidth of the video amplifier. It is used to average or smooth a trace. Refer also to Video Bandwidth.

**VNA** Vector Network Analyzer

---

**W**

**Waveform** A representation of a signal plotting amplitude versus time.

**Wireless** A term that refers to a broad range of technologies that provide mobile communications for home or office, and "in-building wireless" for extended mobility around the work area, campus, or business complex. It is also used to mean "cellular" for in-or out-of-building mobility services.

**WWW** World Wide Web

---

**X**

---

**Y**

---

**Z**

**Zero-Length Through Path** In a measurement calibration, when the two test cables mate together directly without using adapters or a thru-line. See also Non-Insertable Devices.

Differential Amplifier Harmonic Distortion and THD

Physical Setup

Measurement Description

Step 1. Create 5 Differential IQ Channels
Step 2. Define Frequency Ranges
Step 3. Add External Source
Step 4. Define Sources
Step 5. Define and Select Trace Parameters
Step 6. Define X-Axis for each Parameter
Step 7. Calibrate using Cal All Channels

Physical Setup

The two VNA internal sources are used as the differential amplifier inputs.

Connect the inputs to ports 1 and 3 using the same frequency range but with a phase offset of 180°.

Connect the outputs to ports 2 and 4.

Measurement Description

The two VNA internal sources are used as the differential amplifier inputs.
Ch1: Sweep differential-input frequency, measure input and output powers, gain, 2nd and 3rd harmonics (dBc), input match, and total harmonic distortion (THD).

Ch2: Sweep differential-input phase, measure input and output powers, gain, and 2nd harmonic (dBc).

Ch3: Sweep differential-input power to measure gain compression, harmonic powers, and THD.

**Step 1. Create 3 Differential IQ Channels**

On the VNA front panel, press **Meas > S-Param > Meas Class....**

Select Differential I/Q, then either:

- OK delete the existing measurement, or
- New Channel to create the measurement in a new channel.

A Differential I/Q measurement is displayed.

**TIP:** Set up one channel, then use **Copy Channel** to create additional channels (Trace/Chan, Channel, Copy Channel)

**Step 2. Define Frequency Ranges**

All channels will have five ranges.

**Ch 1 (Select to make active)**

Swept Input and harmonic frequencies.

Click Stimulus, then DIQ Setup...

Click New four times for a total of 5 ranges.
Click Edit in each range, then enter the following:

**F1:** 10 MHz to 1.0 GHz; IFBW 1 kHz; Uncheck Couple
**F2:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 2
**F3:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 3
**F4:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 4
**F5:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 5

**Ch 2 and Ch 3**

Fixed Frequencies.

TIP: Set up Ch 2, then use Copy Channel to overwrite channel 3.

Click Stimulus, then DIQ Setup...
Click New four times for a total of 5 ranges.
Click Edit in each range, then enter the following:

**F1:** 50 MHz to 50 MHz (CW); IFBW 1 kHz; Uncheck Couple
**F2:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 2
**F3:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 3
**F4:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 4
**F5:** IFBW 1 kHz; Check Couple; Couple to: F1; Check UP; Multiplier: 5

**Step 3. Add External Sources**

External sources are NOT required for this configuration.

**Step 4. Define Sources**

Click Stimulus, then DIQ Setup...
Learn more about these settings.

Make the following Source settings:

**Ch 1 (frequency sweep)**

<table>
<thead>
<tr>
<th>Source Name</th>
<th>State</th>
<th>Frequency</th>
<th>Power</th>
<th>Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port 1</td>
<td>Auto On</td>
<td>F1</td>
<td>-25.00dBm</td>
<td>0.00°</td>
</tr>
<tr>
<td>Port 2</td>
<td>Off</td>
<td>F1</td>
<td>-5.00dBm</td>
<td>N/A</td>
</tr>
<tr>
<td>Port 3</td>
<td>Auto On</td>
<td>F1</td>
<td>-25.00dBm</td>
<td>180.00°</td>
</tr>
<tr>
<td>Port 4</td>
<td>Off</td>
<td>F1</td>
<td>-5.00dBm</td>
<td>N/A</td>
</tr>
<tr>
<td>Port 1 Src2</td>
<td>Off</td>
<td>F1</td>
<td>-5.00dBm</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Ch2 (phase sweep)**
Note: Do not attempt to control the phase of port 1. It will automatically get set to zero degrees when configured as the reference for port 3.

**Optional Source Configuration Settings**

**Match Correction ON to improve Power Accuracy**

For ALL channels, on the Port 2 dialog:

- Check Match Correction ON.
- Then apply Match Correction for F1, F2, F3, F4.
- "Off+Match" is annotated on the Source setting dialog, although this is NOT shown in the images above.
Decrease Mag/Phase Tolerance and Increase Iterations for Improved Accuracy

On any source in which a Phase setting is made, click Phase Control Setup. Decrease the Tolerance and increase the Max Iterations to improve phase accuracy. Learn more.

Step 5 Define and Select Trace Parameters

Note: Some of the parameters above are NOT displayed. These parameters can be used as diagnostic or troubleshooting parameters. For example, the "M_" terms are created when match correction is applied, but they are not usually displayed directly.

Click Instrument, then Trace, then Add Trace, New Trace..., then Edit Parameters.

Click Load, then navigate to the following VNA folder location to load these parameters:

C:\Users\Public\Documents\Network Analyzer\Samples\Setups\DiffIQ\Diff_Harmonics_THD.xml

Once these parameters are defined, select (check) the parameters for each channel as follows:

Ch1: Ipwr_F1, Opwr_F1, Gain, 2nd_dBc, 3rd_dBc, Sdd11_F1, THD
Ch2: Ipwr_F1, Opwr_F1, Gain, 2nd_dBc
Ch3: Ipwr_F1, Opwr_F1, Opwr_F2, Opwr_F3, Opwr_F4, Opwr_F5, Gain, THD

Step 6. Define X-Axis For Each Parameter

For each channel, click Stimulus, then Sweep, then X-axis Type...

Make the following selections:

<table>
<thead>
<tr>
<th>Channel</th>
<th>X-Axis Domain</th>
<th>X-Axis Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Frequency</td>
<td>F1</td>
</tr>
<tr>
<td>2</td>
<td>Phase</td>
<td>Port 3</td>
</tr>
<tr>
<td>3</td>
<td>Power</td>
<td>Port 1</td>
</tr>
</tbody>
</table>

Step 7. Calibrate using Cal All Channels

Click Response, then Cal, then Cal All...

Select the ports (in circle) for ALL channels.
Differential Amplifier IMD

Physical Setup

Measurement Description
Step 1. Create Differential IQ Channel
Step 2. Define Frequency Ranges
Step 3. Add External Sources
Step 4. Define Sources
Step 5. Define and Select Trace Parameters
Step 6. Define X-Axis for each Parameter
Step 7. Calibrate using Cal All Channels

See All DIQ Examples

Physical Setup

The two PNA internal sources are combined to create one differential amplifier input.

Two external sources are combined to create the other differential amplifier input.
Connect the inputs to ports 1 and 3.
Connect the outputs to ports 2 and 4.
Connect the two external sources to the PNA rear panel as shown above. One external combiner is required.

**Measurement Description**

Ch1: Sweep input frequencies of four signals (two pair of differential signals), measure input and output main-tone powers, third-order lower and upper IM products, and gain of DUT.

**Step 1. Create a Differential IQ Channel**

On the PNA front panel, press Meas, then [Measurement Class]
Select Differential I/Q, then either:
   - OK delete the existing measurement, or
   - New Channel to create the measurement in a new channel.

A Differential I/Q measurement is displayed.

**Step 2. Define Frequency Ranges**

Channel 1 will have five frequency ranges.

**Ch 1**

Swept Input frequencies.

Use the Couple settings to create the following Tone Spacings:
Click Stimulus, then Frequency, then Differential IQ Setup
Click New four times for a total of 5 ranges.
Click Edit in each range, then enter the following:

- **F1 (Tone offset):** 10 MHz to 10 MHz (CW); IFBW 1 kHz; Uncheck Couple
- **F2 (Main Lo In):** 20 MHz to 7 GHz; IFBW 1 kHz; Uncheck Couple.
- **F3 (Main Hi In: F2+F1):** IFBW 1 kHz; Check Couple; Couple to: F2; Offset: F1; Check UP.
- **F4 (IM3Lo: F2-F1):** IFBW 1 kHz; Check Couple; Couple to: F2; Offset: F1; Uncheck UP.
- **F5 (IM3Hi: F3+F1):** IFBW 1 kHz; Check Couple; Couple to: F3; Offset: F1; Check UP.

**Step 3. Add Two External Sources**

Click Utility, then Configure, then External Device Configuration
Click New, then complete the dialog. Learn how.

**Step 4. Define Sources**

Click Stimulus, then Frequency, then Differential IQ Setup
Learn more about these settings.

Make the following Source settings:

**Ch 1 (frequency sweep)**

Do NOT manually set the two external sources to zero degrees. They will get set automatically when configured as reference ports.

Set BOTH external sources to receiver leveling using the R3 receiver as follows:
On the Source Configuration dialog, click Power and Attenuators, then Receiver Leveling.

![Source Configuration dialog](image1)

Select the external source (MXG_N51 in this example).
Then select Receiver name: R3.

**Set Path Configuration**

These settings route the combined sources to the differential input ports.

On the Source Configuration dialog, click Power and Attenuators (shown above), then Path Configuration.

![Path Configuration](image2)

Make the two settings in yellow circles (shown above).

**Optional Source Configuration Settings**

**Match Correction ON to improve Power Accuracy**
For Ports 2 and 4, on the Source Configuration dialog:

Check Match Correction ON.

Then apply Match Correction for F1, F2, F3, F4, F5

"Off+Match" is annotated on the Source setting dialog, although this is NOT shown in the images above.

Decrease Mag/Phase Tolerance and Increase Iterations for Improved Accuracy

On any source in which a Phase setting is made, click Phase Control Setup. Decrease the Tolerance and increase the Max Iterations to improve phase accuracy. Learn more.

Step 5 Define and Select Trace Parameters

Note: Some of the parameters above are NOT displayed. These parameters can be used as diagnostic or troubleshooting parameters. For example, the "M_" terms are created when match correction is applied, but they are not usually displayed directly.
Click Trace/Chan, then Trace, then New Trace, then Edit Parameters.

Click Load, then navigate to the following PNA folder location to load these parameters:

C:\Users\Public\Documents\Network Analyzer\Samples\Setups\DiffIQ\Diff_IMD.xml

Once these parameters are defined, click Trace/Chan, then Trace, then New Trace. Then select (check) the following parameters:

Ch1: PwrMainLoIn, PwrMainHiIn, PwrMainLo, PwrMainHi, Pwr3Lo, Pwr3Hi, ToneGainLo, ToneGainHi

**Step 6. Optional. Define X-Axis For Each Parameter**

For each parameter, click Response, then Measure, then Select X-Axis

**Step 7. Calibrate using Cal All Channels**

Click Response, then Start Cal, then Cal All Channels

![Image of Calibrate All Selected Channels]

Select ports 1 through 4.

**After Calibration, Turn Off Source Cal**

Because the path configuration is different during the measurement as during Cal All, receiver leveling is used to set the correct port powers of the external sources. And since the internal sources are controlled, their power is set relative to the external sources.

Click Response, then Cal, then Power Cal, then Source Correction OFF.
Differential I/Q Modulator

The upconverter has differential IQ, balanced inputs.

Three external generators are required.

The two VNA internal sources are used as the differential I inputs.

- Connect to ports 1 and 3 using the same frequency range.
- Set the phase of port 3 to 180° relative to port 1.

Two external sources are used as the differential Q inputs.

- Connect to ports 2 and 4 using the same frequency range as ports 1 and 3.
- Set the phase of port 2 to +90° relative to port 1.
- Set the phase of port 4 to -90° relative to port 1.

An external RF Source is connected to the LO input. If the LO port is balanced, a balun or 180° hybrid coupler may be used as shown in the example.

- When using a Fixed LO, there is no need to control the source.
- Otherwise, first configure the source in the External Source configuration dialog.

Remove the port 3 front-panel jumper and connect the mixer output to the C receiver input.
This receiver is calibrated using the CPM - Direct Access Receiver Calibration. Learn more.
Differential Mixer

Physical Setup
Measurement Description
Step 1. Create 5 Differential IQ Channels
Step 2. Define Frequency Ranges
Step 3. Add External Source
Step 4. Define Sources
Step 5. Define and Select Trace Parameters
Step 6. Define X-Axis for each Parameter
Step 7. Calibrate using Cal All Channels

See All DIQ Examples
The two VNA internal sources are used as the mixer differential RF inputs.

Connect to Ports 1 and 3 using the same frequency range but with a phase offset of 180°. An external RF Source is connected to the LO input.

When using a Fixed LO, there is no need to control the source. Connect the two IF outputs to Ports 4 and 2.

**Measurement Description**

Ch1: Sweep differential-RF frequency with fixed LO, measure forward input and output powers, forward conversion loss (SC21), differential input match (Sdd11) and LO-to-RF and LO-to-IF feed-through.

Ch2: Sweep differential-IF frequency with fixed LO, measure reverse input and output powers, reverse conversion loss (SC12), differential output match (Sdd22)

Ch3: Sweep differential-RF phase, measure input and output powers and forward conversion loss

Ch4: Sweep differential-RF input power to measure gain compression

**Step 1. Create 4 Differential IQ Channels**

On the VNA front panel, press Meas > S-Param > Meas Class.... Select Differential I/Q, then either:

OK delete the existing measurement, or

New Channel to create the measurement in a new channel.
A Differential I/Q measurement is displayed.

**TIP:** Set up one channel, then use **Copy Channel** to create additional channels (Trace/Chan, Channel, Copy Channel)

### Step 2. Define Frequency Ranges

All channels will have the following ranges:

- **F1:** RF frequencies
- **F2:** LO frequencies
- **F3:** IF frequencies

**Ch 1 and Ch 2 (Select to make active)**

Swept RF and IF; Fixed LO.

**TIP:** Set up Ch 1, then use **Copy Channel** to overwrite channel 2.

- Click Stimulus, then DIQ Setup...
- Click New two times for a total of 3 ranges.
- Click Edit in each range, then enter the following:
  - **F1:** 2.5 GHz to 3.0 GHz; IFBW 1 kHz; Uncheck Couple
  - **F2:** 2.0 GHz to 2.0 GHz (CW); IFBW 1 kHz; Uncheck Couple
  - **F3:** IFBW 1 kHz; Check Couple; Couple to: F1; Offset: F2, Uncheck UP

**Ch 3 and Ch 4**

Fixed RF, IF; and LO.

**TIP:** Set up Ch 3, then use **Copy Channel** to overwrite channel 4.

- Click Stimulus, then DIQ Setup...
- Click New two times for a total of 3 ranges.
- Click Edit in each range, then enter the following:
  - **F1:** 2.75 GHz to 2.75 GHz (CW); IFBW 1 kHz; Uncheck Couple
  - **F2:** 2.0 GHz to 2.0 GHz (CW); IFBW 1 kHz; Uncheck Couple
  - **F3:** IFBW 1 kHz; Check Couple; Couple to: F1; Offset: F2, Uncheck UP

### Step 3. Add One External Source

- Click Instrument, then Setup, then External Hardware, then **External Device**...
- Click New, then complete the dialog. [Learn how](#)

### Step 4. Define Sources

- Click Stimulus, then DIQ Setup...
- [Learn more about these settings](#)

Make the following Source settings:

**Ch 1 (fwd. sweep, fixed 180o offset)**
Ch2 (rev. sweep, fixed 180° offset)

<table>
<thead>
<tr>
<th>Source Name</th>
<th>State</th>
<th>Frequency</th>
<th>Power</th>
<th>Phase</th>

<td>N/A</td>
</tr>
</tbody>
</table>

Ch 4 (I/Q power sweep)
Note: Do not attempt to control the phase of port 1. It will automatically get set to zero degrees when configured as the reference for port 3.

Optional Source Configuration Settings

**Match Correction ON to improve Power Accuracy**

For ALL channels, on the Port 2 dialog:

- Check MatchCorrection ON.
- Then apply Match Correction for ranges (F1, F2, F3)

"Off+Match" is annotated on the Source setting dialog, although this is NOT shown in the images above.
Decrease Mag/Phase Tolerance and Increase Iterations for Improved Accuracy

On any source in which a Phase setting is made, click Phase Control Setup. Decrease the Tolerance and increase the Max Iterations to improve phase accuracy. Learn more.

Step 5 Define and Select Trace Parameters

![New Trace](image)

Note: Some of the parameters above are NOT displayed. These parameters can be used as diagnostic or troubleshooting parameters. For example, the "M_" terms are created when match correction is applied, but they are not usually displayed directly.

Click Instrument, then Trace, then Add Trace, New Trace..., then Edit Parameters.

Click Load, then navigate to the following VNA folder location to load these parameters:

C:\Users\Public\Documents\Network Analyzer\Samples\Setups\DiffIQ\Diff_mixer.xml

Once these parameters are defined, select (check) the parameters for each channel as follows:

Ch1:
Ch2:
Ch3:
Ch4:
Ch5:

Step 6. Define X-Axis For Each Parameter

For each channel, click Stimulus, then Sweep, then X-axis Type...

Make the following selections:

<table>
<thead>
<tr>
<th>Channel</th>
<th>X-Axis Domain</th>
<th>X-Axis Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, 2</td>
<td>Frequency</td>
<td>F1, F3</td>
</tr>
<tr>
<td>3</td>
<td>Phase</td>
<td>Port 3</td>
</tr>
<tr>
<td>4</td>
<td>Power</td>
<td>Port 1</td>
</tr>
</tbody>
</table>

Step 7. Calibrate using Cal All Channels
Click Response, then Cal, then Cal All...

Select the ports (in circle) for ALL channels.

See Cal All for more information.
DIQ Mixer Spurs SE
DIQ Spur Search for Single-ended Mixer

Physical Setup

Measurement Description
Step 1. Create Differential IQ Channel
Step 2. Define Frequency Ranges
Step 3. Add External Sources
Step 4. Define Sources
Step 5. Define and Select Trace Parameters
Step 6. Define X-Axis for each Parameter
Step 7. Calibrate using Cal All Channels

See All DIQ Examples

Physical Setup

Connect the RF input to port 1.
Connect the IF output to ports 2.
Connect the LO to port 3.
### Measurement Description

Ch1: Sweep input frequency and at output, measure LO fundamental and harmonic powers, plus spurs (in dBc relative to the input power), of order n*RF - m*LO, where n and m are integers 1, 2, and 3.

### Step 1. Create a Differential IQ Channel

On the VNA front panel, press **Meas > S-Param > Meas Class....**

Select Differential I/Q, then either:

- OK delete the existing measurement, or
- New Channel to create the measurement in a new channel.

A Differential I/Q measurement is displayed.

### Step 2. Define Frequency Ranges

Channel 1 will have 13 frequency ranges.

Click Stimulus, then DIQ Setup...

Click New 12 times for a total of 13 ranges.

Click Edit in each range, then enter the following:

- **F1 (RF Input):** 3.0 GHz to 3.2 GHz; IFBW 1 kHz; Uncheck Couple
- **F2 (LO):** 2.9 GHz to 2.9 GHz (CW); IFBW 1 kHz; Uncheck Couple.
- **F3 (2*LO):** IFBW 1 kHz; Check Couple; Couple to: F2; Offset: F2; Multiplier: 2. Check UP.
- **F4 (3*LO):** IFBW 1 kHz; Check Couple; Couple to: F2; Offset: F2; Multiplier: 3. Check UP.
- **F5 (1RF - LO):** IFBW 1 kHz; Check Couple; Couple to: F1; Offset: F2; Uncheck UP.

Complete the remaining ranges (F6 to F13) using the above pattern and following formulas:
### Step 3. Add External Sources

This example does NOT use external sources.

### Step 4. Define Sources

Click Stimulus, then DIQ Setup...

Learn more about these settings.

Make the following Source settings:

**Ch 1 (frequency sweep)**

<table>
<thead>
<tr>
<th>Source Name</th>
<th>State</th>
<th>Frequency</th>
<th>Power</th>
<th>Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port 1</td>
<td>Auto On</td>
<td>F1</td>
<td>-15.00dBm</td>
<td>N/A</td>
</tr>
<tr>
<td>Port 2</td>
<td>Off</td>
<td>F1</td>
<td>-5.00dBm</td>
<td>N/A</td>
</tr>
<tr>
<td>Port 3</td>

<td>N/A</td>
</tr>
<tr>
<td>Port 1 Src2</td>
<td>Off</td>
<td>F1</td>
<td>-5.00dBm</td>
<td>N/A</td>
</tr>
</tbody>
</table>

This example does NOT use phase control.

**Optional Source Configuration Settings**

**Match Correction ON to improve Power Accuracy**

For Port 2 and 4, on the Source Configuration dialog:

Check Match Correction ON.

Then apply Match Correction for all ranges.

"Off+Match" is annotated on the Source setting dialog, although this is NOT shown in the images above.
Step 5 Define and Select Trace Parameters

Note: Some of the parameters above are NOT displayed. These parameters can be used as diagnostic or troubleshooting parameters. For example, the “M_” terms are created when match correction is applied, but they are not usually displayed directly.

Click Instrument, then Trace, then Add Trace, New Trace..., then Edit Parameters.

Click Load, then navigate to the following VNA folder location to load these parameters:

C:\Program Files\Keysight\Network Analyzer\Documents\Templates\Samples\Setups\DiffIQ\Mixer_spurs.xml

Once these parameters are defined, click Instrument, then Trace, then Add Trace, New Trace... Then select (check) ALL parameters.

Step 6. Optional. Define X-Axis For Each Parameter

For each parameter, click Stimulus, then Sweep, then X-axis Type...

Step 7. Calibrate using Cal All Channels
Click Response, then Cal, then Cal All...

Select ports 1 through 3.

Step 2. Define Frequency Ranges
Step 3. Add External Source
Step 4. Define Sources
Step 5. Define and Select Trace Parameters
Step 6. Define X-Axis for each Parameter
Step 7. Calibrate using Cal All Channels

See All DIQ Examples

Physical Setup

IQ signals normally contain digital information, but when tested with a network analyzer, are simple sinusoidal signals.

LO is used as the RF carrier signal.
RF is the modulated output.
The two VNA internal sources are used as the converter’s quadrature inputs.

Connect to ports 1 and 3 using the same frequency range but with a phase offset of 90°.
An external RF Source is connected to the LO input(s).

When using a Fixed LO, there is no need to control the source.
Connect the output to port 2.

Measurement Description

Ch1: Sweep I/Q frequencies with fixed LO; at RF output, measure LO+I/Q and LO-I/Q sideband frequency response, image rejection (upper-sideband/lower-sideband), and LO leakage.

Ch2: Sweep Q phase at fixed I/Q, LO, and RF frequencies; measure sidebands.

Ch3: Sweep I power at fixed I/Q, LO, and RF frequencies; measure sidebands.

Ch4: Sweep LO frequency with fixed I/Q input frequencies; measure sidebands.

Ch5: Sweep I/Q power at fixed I/Q, LO, and RF frequencies; measure sideband compression.

Step 1. Create 5 Differential IQ Channels

On the VNA front panel, press **Meas > S-Param > Meas Class....**
Select Differential I/Q, then either:
  - OK delete the existing measurement, or
  - New Channel to create the measurement in a new channel.
A Differential I/Q measurement is displayed.
**Step 2. Define Frequency Ranges**

All five channels will have the following ranges:

- **F1**: I/Q frequencies
- **F2**: LO frequencies
- **F3**: Upper sideband frequencies (F2 + F1)
- **F4**: Lower sideband frequencies (F2 - F1)

**Ch 1 (Select to make active)**

Click Stimulus, then DIQ Setup...

Click New three times for a total of 4 ranges.

Click Edit in each range, then enter the following:

- **F1**: 10 MHz to 2.4 GHz; IFBW 1 kHz; Uncheck Couple
- **F2**: 2.5 GHz to 2.5 GHz (CW); IFBW 1 kHz; Uncheck Couple
- **F3**: IFBW 1 kHz; Check Couple; Couple to: F2; Offset: F1, Check UP
- **F4**: 2.49 GHz to 100 MHz; IFBW 1 kHz; Uncheck Couple

**Ch 2, Ch 3, and Ch 5**

**TIP**: Set up Ch 2, then use **Copy Channel** to overwrite channels 3 and 5.

Click Stimulus, then DIQ Setup...

Click New three times for a total of 4 ranges.

Click Edit in each range, then enter the following:

- **F1**: 1.2 GHz to 1.2 GHz (CW); IFBW 1 kHz; Uncheck Couple
- **F2**: 2.5 GHz to 2.5 GHz (CW); IFBW 1 kHz; Uncheck Couple
- **F3**: 3.7 GHz to 3.7 GHz (CW); IFBW 1 kHz; Uncheck Couple
- **F4**: IFBW 1 kHz; Check Couple; Couple to: F2; Offset: F1, Uncheck UP

**Ch 4**

Click Stimulus, then DIQ Setup...

Click New three times for a total of 4 ranges.

Click Edit in each range, then enter the following:

- **F1**: 500 MHz to 500 MHz (CW); IFBW 1 kHz; Uncheck Couple
- **F2**: 1.0 GHz to 4.4 GHz; IFBW 1 kHz; Uncheck Couple
- **F3**: 1.5 GHz to 4.9 GHz; IFBW 1 kHz; Uncheck Couple
- **F4**: 500 MHz to 3.9 GHz; IFBW 1 kHz; Uncheck Couple

**Step 3. Add External Sources**

Click Instrument, then Setup, then External Hardware, then External Device...

Click New, then complete the dialog. Learn how.

**Step 4. Define Sources**
Click Stimulus, then DIQ Setup...

Learn more about these settings.

Make the following Source settings:

**Ch 1 and 4 (fixed 90° offset)**

</tbody>
</table>

**Ch 5 (I/Q power sweep)**
Note: Do not attempt to control the phase of port 1. It will automatically get set to zero degrees when configured as the reference for port 3.

Optional Source Configuration Settings

**Match Correction ON to improve Power Accuracy**

For ALL channels, on the Port 2 dialog:

- Check Match Correction ON.
- Then apply Match Correction for measurements of LO and sidebands (F2, F3, F4)

"Off+Match" is annotated on the Source setting dialog, although this is NOT shown in the images above.
Decrease Mag/Phase Tolerance and Increase Iterations for Improved Accuracy

On any source in which a Phase setting is made, click Phase Control Setup. Decrease the Tolerance and increase the Max Iterations to improve phase accuracy. Learn more.

Step 5 Define and Select Trace Parameters

Click Instrument, then Trace, then Add Trace, New Trace..., then Edit Parameters.

Then do one of the following to create these Diff I/Q measurement parameters:

Click Load, then navigate to the following VNA folder location to load these parameters:

C:\Users\Public\Documents\Network Analyzer\Samples\Setups\DiffIQ\IQ_up_converter.xml

Use the Edit Parameters dialog to manually create these parameters.

Use a text editor to create an *.xml file. Learn how.

Once these parameters are defined, select (check) the parameters for each channel as follows:

Ch1: LO+I/Q, LO-I/Q, Image rejection, LO leakage
Ch2: LO+I/Q, LO-I/Q, Image rejection
Ch3: LO+I/Q, LO-I/Q, Image rejection
Ch4: LO+I/Q, LO-I/Q
Ch5: LO+I/Q, LO-I/Q, LO+I/Q com

Step 6. Define X-Axis For Each Parameter

For each channel, click Stimulus, then Sweep, then X-axis Type...

Make the following selections:
<table>
<thead>
<tr>
<th>Channel</th>
<th>X-Axis Domain</th>
<th>X-Axis Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Frequency</td>
<td>F1</td>
</tr>
<tr>
<td>2</td>
<td>Phase</td>
<td>Port 3</td>
</tr>
<tr>
<td>3</td>
<td>Power</td>
<td>Port 1</td>
</tr>
<tr>
<td>4</td>
<td>Frequency</td>
<td>F2</td>
</tr>
<tr>
<td>5</td>
<td>Power</td>
<td>Port 1</td>
</tr>
</tbody>
</table>

**Step 7. Calibrate using Cal All Channels**

Click Response, then Cal, then Cal All...

Select the ports (in circle) for ALL channels.
Noise Figure with External Testset

The low-noise receiver and the noise receiver path switch is added between the port 2 CPLR THRU jumper connector and the port 2 bias tee as shown in the images below.

When it is configured with a multiport test set (i.e. U3024AH10), the low-noise receiver cannot be used with test ports on the test set with standard multiport test set jumper connections. See the following modified test set connections to use 50 GHz low-noise receiver with multiport test set.

50 GHz 2-port Noise Figure Components (shaded in yellow)
Standard Connections

Modified Connections w/External Coupler

2-port coupler used with 50 GHz Opt. 029 (low-noise receivers) with multiport test set.
4-port coupler used with 50 GHz Opt. 029 (low-noise receivers) with multiport test set.
Swept IMD Configure External Source and Combiner

Configure an External Source and Combiner for Swept IMD Measurements using the N522xB Models

The following configurations can be used on the N522xB models for use with the IMD Apps (Swept IMD, IMDx, IM Spectrum, and IMx Spectrum).

- N522xB 2-port models
- N522xB 4-port models using Internal Components
- N522xB 4-port models using External Components

These are NOT the only supported configurations, but are intended to be used as examples. However, base N522xB models (without front-panel jumpers) are NOT supported with the IMD Apps.

See Also

- N522xB Specs - Block diagrams appear in the last pages.
- N522xB Models and Options

N522xB 2-port models (Single source; no internal combiner)

Required

- **External Source** - see list of supported sources.
- **Combiner** - Used to combine f1 (from internal source) and f2 (from external source).
- **Coupler** - Used to route input tones to R1 receiver.
- **Cables** - Used to make connections as shown in image.

Notes
The R1 reference switch MUST be set to "External". Press Setup > External Hardware > External Testset. R1 receiver is used to measure both the $f_1$ and $f_2$ tones. R1 is inferred by the VNA when you select Port 1 as the DUT input on the IMD Setup dialog Power tab. Connection at 'd' above is to measure DUT input reflections at receiver A.

**Procedure**

Remove the front-panel jumpers with labels in above image. Configure the setup as shown in above image.

In the External Source Configuration dialog, configure the external source.

In the IMD Setup dialog; Configuration tab, select the external source as f2 tone.

---

**N522xB 4-port models using internal VNA components**

Port 3 coupler is used to combine $f_1$ and $f_2$.

Port 4 coupler is used as a splitter to route the tones to the R1 receiver.

You can also use external components for one or both of these functions for less loss or better power-handling capability.

This configuration can also be used for 4-port PNA-X models with no internal combiner.
Required

Cables - Used to make connections as shown in image.

Notes

R1 receiver must measure both the \( f_1 \) and \( f_2 \) tone. R1 is inferred by the VNA when you select Port 1 as the DUT input on the IMD Setup dialog Power tab.

Connection at 'c' above is to measure DUT input reflections at receiver A.

Procedure

Remove the front-panel jumpers that have labels in above image. Not all front-panel connectors will be cabled when finished.

Configure the setup as shown in above image. Be sure to make connections to ALL four VNA test ports as shown in about image.

N522xB 4-port models using External Components

This configuration can also be used for 4-port PNA-X models with no internal combiner.
Required

**Combiner** - Used to combine $f_1$ and $f_2$.

**Coupler** - Used to route input tones to R1 receiver.

**Cables** - Used to make connections as shown in image.

Notes

R1 receiver is used to measure both the $f_1$ and $f_2$ tones. R1 is inferred by the VNA when you select Port 1 as the DUT input on the IMD Setup dialog Power tab.

Connection at 'c' above is to measure DUT input reflections at receiver A.

Procedure

Remove the front-panel jumpers with labels in above image.

Configure the setup as shown in above image.
**SweptIMDLimitedPortMapping**

The IMD, IMDx, IMSpectrum, and IMxSpectrum Apps have a limited port mapping capability. This would allow you, for example, to simultaneously measure two 2-port DUTs in different channels. You could input the 2-tone signal to port 1 and port 3. The DUT output would be connected to port 2 and port 4.

Port selections are made on the Power Tab for each Application.

**Note:** This setup requires an external combiner connected to the rear-panel. The external combiner that is shown has two inputs and two outputs. This can also be accomplished by using two components.

This example setup shows a 4-port transceiver connected to the VNA ports as follows:

<table>
<thead>
<tr>
<th>VNA Port</th>
<th>DUT Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Rx In</td>
</tr>
<tr>
<td>2</td>
<td>Rx Out</td>
</tr>
<tr>
<td></td>
<td>Tx In</td>
</tr>
<tr>
<td>---</td>
<td>-------</td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Tx Out</td>
</tr>
</tbody>
</table>

**Notes**

When DUT Input = VNA port 1, then DUT Output = VNA port 2 (default) OR port 4.
When DUT Input = VNA port 3, then DUT Output = VNA port 4.
Each port mapping configuration must be setup in separate channels.
The input and output frequencies for each channel can be at different frequencies.
The Path Configuration settings are made automatically.
Calibration is performed normally using the IMD Cal Wizard.
Because an external combiner is used, input power to the DUT must be monitored by you to ensure that the DUT is not being overdriven.
Both input tones must be supplied by the internal VNA sources.
A mixer LO can be a VNA internal source, an external source, or an embedded LO.
Critical Information

During boot up of Windows or of the Network Analyzer application program, do NOT press keys on the front panel, rotate the RPG knob, or connect a USB device. Doing so MAY lead to a front panel lockup state. To clear this state; **Shutdown and Restart** (do not Hibernate) the VNA.

**Prevent Damage to your VNA Hard Disk Drive.**
**Follow proper VNA Shutdown procedures.**
**Perform Display Test to see if your VNA meets specification.**
**See DC Voltage damage levels for your VNA model.**
**See Preventing Electrostatic Damage on your VNA**
**See Preventing Test Port Connector Damage**
**See Extremely Fragile N5247B front-panel loops**

The VNA does NOT have antivirus protection when shipped. Use of an antivirus program is strongly recommended if you connect the VNA to the Internet.

We no longer sell VNA printed manuals. However, several printable versions of VNA Help in pdf format are available at [http://na.support.keysight.com/pna/help/](http://na.support.keysight.com/pna/help/)
Home Frequency Offset Measurements

Frequency Offset measurements require the VNA source to tune to a different frequency than the VNA receiver.

This capability is offered as an option on some VNA models.

To view the options that are installed on your VNA, click Help then About Network Analyzer.

- **Frequency Offset (Option S93080A)** - Allows basic frequency converter measurements.
- **Frequency Converter Application (Option S93083A/B)** - Allows you to easily make extremely accurate scalar and phase frequency converter measurements.
- **Tutorials** - Learn how to make specific Frequency Conversion Device Measurements.

SMC

FCA Overview
SMC Measurements
Mixer Converter Setup
Frequency Offset Mode
Front Panel Jumpers

There are many reasons to configure the front-panel jumpers on the VNA.

- High-power measurements using the VNA - App Note 1408-10
- Using a Booster Amp for SMC Measurements
- Improving Dynamic Range

**Note: Phase-locking and the Reference Receivers**

The R1 and R2 reference receivers are used for phase-locking between the RF source and receiver LO. The phase-locking requirement imposes the following restrictions on the reference signal:

- **PNA-X and N522x** power level: limited by the noise floor
- All models require a clean signal without spurious content

In Frequency Offset Mode (FOM) Opt S93080A, the R1 receiver is NOT used for phase locking. Independent internal circuitry is used to phase lock the source and receivers. When FOM is available, turn FOM ON simply to take advantage of the independent phase locking mechanism. If NOT measuring at different source and receiver frequencies, set the offset to zero, so that the source and receiver frequencies are the same.

Accessing Data

Click a box or circle to view details:

See 8510 data processing mode.
See larger Data Processing map.

Measurement - Receivers gather complex trace data which is ratioed if required by the parameter, such as S11 or A/B. Otherwise it is raw receiver data, such as A or B. See Measurement Parameters.

Averaging - If turned ON, data is averaged with specified number of measurement traces. See Averaging.

Data Access Point 0 - Get or Put RAW MEASUREMENT data using:

SCPI - Write data using Calc:Data SDATA - Read data from Data Access Point 1

COM - getData and putDataComplex - naRawData (0)

Formatting Note:

COM - getData allows you to request data from locations 0 to 5 in a format other than the displayed format. SMOOTHED data is only attainable from locations 2 & 4, and only when you request data in the same format as the displayed format.

SCPI: you can only request data in the displayed format.

Acquired Cal Data - Calibration standards are measured. When the calibration is complete, complex data is stored in a Cal Set.

Data Access Point 6 - Get or Put RAW CAL ACQUISITION data using:

SCPI - None

COM - getStandardComplex and putStandardComplex

Calculate Error Terms - Error terms are calculated from Acquisition data using formulas which are appropriate for the selected calibration method. Complex error terms are stored in a Cal Set. See Systematic Errors.

Data Access Point 5 - Get or Put ERROR TERM data using:

SCPI - Calc:Data Error Terms

COM - Error Term commands

Note: Normalization, formerly access location 5, no longer exists and was used ONLY by Receiver Power Cal. That cal type now uses Acquire Cal Data and Calculate Error Terms like all other Cals.
Apply Error Terms - If error correction is ON, error terms are applied to the raw measurement data. Otherwise, this data is identical to Raw Measurement Data. In addition, the Fixture Simulator functions occur at the same time as the Apply Error Terms block.

**Data Access Point 1** - Get or Put CORRECTED data using:

- **SCPI** - Read data using **Calc:Data SDATA** - Write data to Data Access Point 0
- **COM** - **getData** and **putDataComplex** - naCorrectedData (1)

See Formatting Note

---

**Equation Editor** - Allows custom equations to perform advanced math operations between data traces. See Equation Editor Notes:

- **SCPI**: Calc:Data
- **COM**: Get Data Method or Get DataByString Method.

---

**Normalization** - No longer available

**Data Access Point 5** - No longer available

---

**Trace Math** - When turned ON, memory data is combined with measurement data using the selected math function. Available functions are: Data+Mem, Data-Mem, Data*Mem, and Data/Mem. See Math Operations.

---

**Memory** - Data that is stored as a result of a Data-To-Memory operation. Each measurement can have one memory trace. The memory data parallels the measurement data through the remaining processing blocks. For example, turning smoothing ON will smooth both the measurement and memory traces.

**Data Access Point 3** - Get or Put MEMORY data using:

- **SCPI** - Calc:Data SMEM
- **COM** - **getData** and **putDataComplex** - naRawMemory (3)

See Formatting Note

---

**Gating** - When turned ON, Filter Gating is applied to the measurement data. Gating "virtually" removes undesired responses from selected regions of the trace. See Gating.

---

**Phase Correction** - When turned ON, applies electrical delay, phase offset, and port extensions. These are all separate features that are controlled individually.
**Magnitude Offset** - When entered, offset values are applied to the magnitude (real) portion of the data. See Magnitude Offset.

**Time Domain** - When turned ON, transforms the data from the frequency domain to the time domain. See Time Domain

**Formatter** - Complex data is converted into scalar data formats for screen display and remote access. For smoothed data, request the data in the same format as the displayed data. See Data Format

**Smoker** - When turned ON, removes discontinuities in the measurement and memory trace. See Smoothing.

**Display** - Displays the processed measurement, memory data, or both, in the format of your choice.

**Data Access Point 2** - Get or Put MEAS RESULT data using:

- **SCPI** - `Calc:Data FDATA`
- **COM** - `getData` and `putDataComplex` - `naMeasResult (2)`

**Data Access Point 4** - Get or Put MEMORY RESULT data using:

- **SCPI** - `Calc:Data FMEM`
- **COM** - `getData` and `putDataComplex` - `naMemoryResult (4)`

See Formatting Note

CF_Cal Commands

The Cal softkeys vary depending on which measurement class is currently active. Click on a measurement class link below to view the corresponding softkeys.

- Standard
- Active Hot Parameters
- Gain Compression and Gain Compression Converters
- Differential I/Q
- IM Spectrum and IM Spectrum Converters
- Swept IMD and Swept IMD Converters
- Modulation Distortion and Modulation Distortion Converters
- Noise Figure Cold Source and Noise Figure Converters
- Phase Noise
- Scalar Mixer/Converter + Phase and Vector Mixer/Converter
- Spectrum Analyzer

CF_Cal Commands - MOD

Cal Commands - Modulation Distortion and Modulation Distortion Converters Measurement Class

Only the Main Cal commands corresponding to the Modulation Distortion and Modulation Distortion Converters measurement class are documented here. All other commands are identical to the Cal commands for the Standard measurement class and can be accessed by clicking here or by clicking on the softtabs on the graphic below.

Click here to view links to Cal commands for all Measurement Classes.

CF_Freq Commands

The Freq softkeys vary depending on which measurement class is currently active. Click on a measurement class link below to view the corresponding softkeys.

Standard
Active (Hot) Parameters
Gain Compression
Differential I/Q
IM Spectrum and IM Spectrum Converters
Swept IMD and Swept IMD Converters
Modulation Distortion and Modulation Distortion Converters
Noise Figure Cold Source
Phase Noise
Gain Compression Converters and Noise Figure Converters
Scalar Mixer/Converter + Phase and Vector Mixer/Converter
Spectrum Analyzer

CF_Meas Commands

The Meas softkeys vary depending on which measurement class is currently active. Click on a measurement class link below to view the corresponding softkeys.

Standard

Active Hot Parameters

Gain Compression

Differential I/Q

IM Spectrum

Swept IMD and Swept IMD Converters

Modulation Distortion and Modulation Distortion Converters

Noise Figure Cold Source

Phase Noise

Gain Compression Converters

IM Spectrum Converters

Noise Figure Converters

Scalar Mixer/Converter + Phase

Vector Mixer/Converter

Spectrum Analyzer

TDR (Time Domain Reflectometry)
CF_Meas Commands - DIQ
